ABSTRACT

In this work, density, vapor-liquid equilibrium and speed of sound measurements of the mixtures [CO₂+4.72 mol% SO₂+1.85 mol% CH₄] and [CO₂+0.09 mol% SO₂+1.54 mol% CH₄] were performed over the temperature range 263-373 K and at pressures of up to 30 MPa for density and up to 190 MPa for speed of sound. For the speed of sound measurements, the mixtures were doped with \cong 0.8 mol% CH₃OH. We compared our results to the values calculated using an extended version of the equation of state for combustion gases (EOS-CG) that includes binary models for the CO₂+SO₂ and CO₂+CH₄ subsystems, and a perturbed-chain statistical associating fluid theory (PC-SAFT) equation of state, validating both equations in this way. From our experimental results, we evaluated the impact of the simultaneous presence of SO₂ and CH₄ as impurities in anthropogenic CO₂ on selected parameters for carbon capture and storage technology. With the understanding that chemical effects have not been considered, we concluded that the presence of 4.72 mol% SO₂ compensates for the negative effect of 1.85 mol% CH₄ on most of the studied

parameters, resulting in a favorable fluid for carbon capture and storage, contrary to the mixture with 0.09 mol% SO₂ and 1.54 mol% CH₄.

Keywords: CO₂, SO₂, CH₄, density, speed of sound, VLE, equation of state, CCS, saline aquifer storage.

1. INTRODUCTION

Fossil fuel combustion in the power generation sector is a major source of anthropogenic CO₂, and significant amounts of this fluid are produced as well in oil and gas processing [1]. Global CO₂ emissions are expected to rise by more than 2% in 2018 [2]. To reach the Paris 2°C scenario, approximately 4 Gt of CO₂ per year must be captured and stored by 2040, which is 100 times more than the current annual storage capacity [3]. Thus, anthropogenic CO₂ should be captured at emitting facilities, conditioned and transported for disposal in adequate geological reservoirs – carbon capture and storage (CCS)– or utilization in industrial or CO₂-enhanced oil recovery (CO₂-EOR) projects [4].

CO₂ capture technologies aim to produce CO₂ that is as pure as possible, but in practice, the CO₂ obtained will contain a few percent of impurities/contaminants. The cleaner the CO₂ obtained, the lower the efficiency of the capture process will be [5].

CO₂, SO₂ and CH₄ are components of CCS and CO₂-EOR [6,7]. SO₂ is a very toxic impurity coming mainly from the burning of sulfur-containing fuels; recent studies have indicated that it benefits some aspects of operation at CCS facilities, and CO₂/SO₂ co-capture has been proposed [8-12]. CH₄, coming for instance from coal gasification processes, is one of the most powerful greenhouse gases; its comparative impact is more than 25 times greater than that of the same mass of CO₂ over a 100-year period [13]. We consider in this work the possibility of mixing and joint management of emissions from different sources, what could lead to the simultaneous presence of

both impurities in the CCS or EOR facilities. The thermodynamic and hydraulic study carried out in this work helps to decide if CO₂/SO₂ cotransport, coinjection and costorage in presence of CH₄ is appropriate, thus avoiding CO₂, SO₂ and CH₄ emissions into the atmosphere and reducing purification costs. To our knowledge, thermodynamic data of multicomponent mixtures containing CO₂, SO₂ and CH₄ under conditions relevant to these technologies are missing from the literature. These data are needed to be able to select and validate the models that allow calculation of a fluid's physical properties to carry out the design and operation of such processes.

Thus, the first aim of the present study was the experimental determination of new and accurate pressure-density-temperature, $p\rho T$; vapor–liquid equilibrium, VLE; and pressure-speed of sound-temperature, pcT , data for two CO₂+SO₂+CH₄ mixtures: the “co-capture” mixture contained impurity concentrations corresponding to different emissions from some energy processes without further purification [10], and the “emissions” mixture contained SO₂ and CH₄ concentrations which were equivalent to the total releases of SO₂ and CH₄ from the European Union (EU), calculated using the data for the total emissions in the EU of the gases inventoried in Ref. [14].

The working temperature varied from 263 to 373 K, and the pressure was up to 30 MPa for the density measurements and up to 190 MPa for the speed of sound measurements. For the speed of sound measurements, the mixtures were doped with $\cong 0.8$ mol% CH₃OH, given their opacity to sound at 5 MHz (which is our working frequency) in most of the studied ranges of conditions (see Section 3.1) [8,9,15]. Despite the doping, the apparatus did not provide proper signals in the low-pressure range. As low-pressure values are important for CCS and CO₂-EOR, experimental pcT data were used to obtain extrapolated c values at lower pressures. These data are necessary, along with density information, to calculate other thermodynamic properties, such as the heat capacity at constant pressure and the Joule-Thomson coefficient of the mixtures, which are used to

determine the thermal behavior of the fluid during depressurization, either operational or accidental.

The experimental conditions in this work extend those of CCS and CO₂-EOR because the second aim of this work was to evaluate two equations of state, EoSs, as predictive models: an extended EoS for combustion gases (a recent and unpublished version of the original EOS-CG [16]), as implemented in the available TREND 3.0 software [17] and a perturbed-chain statistical associating fluid theory (PC-SAFT) EoS [18]. For this purpose, we compared our experimental data with those provided by these EoSs. Binary mixture data are needed to adjust the parameters of these models. Thus, the authors carried out [8,9,15,19-21] an experimental study of the volumetric, VLE, and acoustic behaviors of CO₂-rich binary systems with SO₂ or CH₄ at pressures and temperatures corresponding to the gas, liquid and supercritical states.

The third aim of the present work was to study the impact of the simultaneous presence of SO₂ and CH₄ as impurities in CO₂ transport, injection and storage with different concentrations and to evaluate the feasibility of CO₂/SO₂ co-capture in presence of CH₄, which reduces conditioning costs and helps avoid the SO₂ and CH₄ emissions into the atmosphere. For this purpose, we calculated several technical-operational CCS parameters for transport, injection and storage and discussed the behaviors of the studied mixtures in relation to these parameters, compared with the behaviors of pure CO₂ and of the CO₂+SO₂ and CO₂+CH₄ mixtures containing the same amounts of impurities [8,9,15,20,21]. Moreover, we used the experimental data of the ternary mixtures prepared in this work and of binary mixtures [8,9,15,20,21] to evaluate how seven selected reservoirs [22-28] (Table 1) would be affected by the presence of the studied impurities in the injected fluid. Our study is based on thermodynamic and hydraulic factors. Other factors, such as the chemical effects of the impurities, which have not been considered, must also be taken into

account to draw global conclusions about both the fluid quality requirements for the safe design and operation of CCS facilities and the feasibility of CO₂/impurity co-capture.

To the best of our knowledge, the CO₂+SO₂+CH₄ system has never been investigated, and the main goal of this work is to experimentally study the volumetric, VLE and acoustic behavior of this system under conditions relevant to different technologies, mainly CCS. Moreover, the discussion of these data in terms of the evaluation of two EoSs with wide applicability and the impact of the simultaneous presence of SO₂ and CH₄ in CO₂ transport, injection and storage will help to achieve the expected deployment of the technologies to reduce CO₂ emissions and thus to mitigate climate change.

2. MATERIALS AND METHODS

2.1 Materials. CO₂, SO₂ and CH₄ (mole fractions > 0.99998, 0.9990 and 0.99995, respectively) were purchased from Air Liquide and used as received. CH₃OH (biotech grade, mole fraction 0.9993) from Sigma Aldrich was degassed immediately before use.

2.2. Apparatus and methods. Given the hazard of the investigated gases –SO₂ is a toxic gas, and CH₄ is a combustible gas– and the high pressure used in this work, safety measures were incorporated into the experimental installations used, including hoods and polycarbonate

transparent barriers around the experimental facilities and safety equipment, such as portable self-contained breathing apparatuses and leak detectors.

Table 2 presents the values of the mole fraction composition, x_i , and its combined standard uncertainty, $u(x_i)$, for the mixtures studied in this work. The mixtures were prepared gravimetrically, and the components were introduced in the order of increasing volatility in a variable-volume cell (maximum volume of 0.51 L and maximum working pressure of 30 MPa). The procedures for preparing the mixtures and transferring them to the experimental installations are described in Ref. [9]. CH₃OH (used as a dopant for c measurements) was degassed once inside the cell via 3 h of intermittent vacuuming with agitation.

Table 2. Mole fraction composition, x_i , and its combined standard uncertainty, $u(x_i)$, for the mixtures studied in this work.

The combined standard uncertainty values for the experimental data obtained in this work are calculated according to the “Evaluation of Measurement Data – Guide to the Expression of Uncertainty in Measurement (GUM)” [29] suggested by the National Institute of Standards and Technology (NIST).

The $u(x_i)$ of each component in the mixtures was estimated from [30]:

$$u(x_i) = \left[\frac{1}{\sum_{j=1}^N n_j} \right] \sqrt{(1 - 2x_i)u(n_i)^2 + x_i^2 \sum_{j=1}^N u(n_j)^2} \quad (1)$$

where n_i is the number of moles of component i added to the mixture based on the change in the mass of the system. The masses were determined by successive weighing in a comparator balance from Sartorius, model CCE 2004, with a repeatability better than 0.0002 g. The standard uncertainty in the calculated number of moles, $u(n_i)$, of each substance was estimated based on the standard uncertainty of the individual mass measurements and on the estimated uncertainty due to the presence of impurities in the pure gases used.

The experimental installation and procedure used to obtain the $p\rho T$ data were detailed in previous publications [9,19,31]. The main component of the installation is an Anton Paar DMA HPM vibrating-tube densimeter connected to an MPDS V3 evaluation unit. The fluid flow of 0.005 MPa·s⁻¹ used during the $p\rho T$ isotherm determination ensures quasistatic experiments and measurements at thermodynamic quasiequilibrium, as indicated by the designers of the apparatus [32]. The device operates at temperatures from 263 K to 423 K and at pressures of up to 70 MPa. The temperature was measured using two 100 Ω platinum probes, which were calibrated before the experimental measurements in this work by the Centro Español de Metrología, CEM [33]. The estimated standard uncertainty in temperature, $u(T)$, was 0.006 K. The stability of temperature during the measurement of a $p\rho Tx_{\text{CO}_2}$ isotherm was better than ±0.04 K. The pressure was determined using two pressure transducers (GE Infrastructure model PTX 611), which were calibrated in our laboratories using a Wika CPH 6000 calibrator, with an accuracy of 0.025% over the whole scale. The obtained combined standard uncertainty in pressure, $u(p)$, was 0.0020 MPa for $p < 6$ MPa and 0.024 MPa for $6 \text{ MPa} \leq p \leq 70$ MPa [34]. The vibrating tube was calibrated with pure CO₂ at temperatures from 263.15 to 373.15 K and pressures of up to 70 MPa, with results similar to those obtained during the start-up of the installation [31]. The procedure to calculate the combined standard uncertainty in density, $u(\rho)$, for the studied mixtures is the same as that

described in Ref. [10]. The values of $u(\rho)$ are included in the Supplementary Material, SM, Tables S1 and S2, and range from 0.22 to 0.40 kg/m³.

The VLE limits, dew pressure and bubble pressure, p_{dew} and p_{bubble} , respectively; the densities of the vapor, ρ_V , and liquid, ρ_L , phases in the VLE; and their combined standard uncertainties included in Table S3 were determined from the quasicontinuous $p\rho T$ data using the tangents method proposed by the designers of the experimental setup [9,32]. The combined uncertainty values of the VLE data range from 0.0025 to 0.044 MPa for pressure and from 0.48 to 1.9 kg·m⁻³ for density. The speed of sound measurements were performed using a previously described 5 MHz pulsed ultrasonic system [15]. The apparatus operates from 253 K to 473 K, with $u(T) = 0.015$ K. The maximum achievable pressure is 200 MPa, and the $u(p)$ is 0.02 Mpa. The mixtures were doped with $\cong 0.8$ mol% CH₃OH to obtain proper signals at lower pressures [15]. The combined standard uncertainty of the experimental c values, $u(c)$, was calculated using the following equation [15,35]

$$(u(c))^2 = \left[(\partial c / \partial T)_{p,x} u_T \right]^2 + \left[(\partial c / \partial p)_{T,x} u_p \right]^2 + \left[(\partial c / \partial x)_{p,T} u_x \right]^2 + (u^*(c))^2 \quad (2)$$

where $u^*(c)$ is the standard repeatability uncertainty, which depends on the studied system. To determine $u^*(c)$ for the CO₂+CH₃OH+SO₂+CH₄ system, two mixtures with co-capture compositions were prepared (values of x_i and $u(x_i)$ are provided in Table S4). For each mixture, at least two isotherms were determined at each of the temperatures (263, 293 and 313 K) at an overall range of pressures from 15.20 to 191.12 MPa (Table S5). The value determined for $u^*(c)$ was $7.4 \times 10^{-4} \cdot c$, and the overall combined standard uncertainty of c was $u(c) = 7.4 \times 10^{-4} \cdot c$. These values lie within the range of standard uncertainties published for liquid mixtures and mixtures of compressed gases using a similar apparatus [15].

3. RESULTS AND DISCUSSION

In this section, we present the experimental and calculated results obtained in this work (3.1), and we discuss the predictive capability of the extended EOS-CG and PC-SAFT EoS to reproduce them (3.2) and the influence of SO₂ in the presence of CH₄ on several transport, storage and injection parameters (3.3). Moreover, the effect of SO₂ and CH₄ in the injected fluid under real T and p conditions corresponding to seven selected saline aquifers (Table 1) is also discussed (3.3.2).

3.1 Results

We measured 8 $p\rho T$ isotherms per mixture for Mixtures 1 and 3, as shown in Table 2. The density measurements were performed at nominal temperatures of $T = 263.15, 273.15, 293.15, 304.21$ and 313.15 K at pressures of up to 20 MPa and at nominal temperatures of $T = 333.15, 353.15$ and 373.15 K at pressures of up to 30 MPa (Figure 1 and Figure S1). The total number of points was $\approx 19,000$, and these data are available in Table S1. A smaller number of points is presented in Table S2 to facilitate their further use. The T and p ranges were chosen considering the operating conditions during transport by the pipeline [36-39], injection and storage, including the conditions in most geological storage sites [7,22,40,41]. Mixture 1 (co-capture) has greater x_{SO_2} and x_{CH_4} values than Mixture 3 (emissions). SO₂ is a “condensable” impurity, and its presence in the mixtures results in an increase in density compared to that of pure CO₂ [8, 9, 42]. Conversely, CH₄ is a “noncondensable” impurity, which leads to density decreases [20, 21, 42]. Figure S2 shows that the density of Mixture 1 is greater than that of pure CO₂, ρ_0 , which in turn is greater than the density of Mixture 3 at a given T and p . Therefore, the effect of CH₄ on the density is counteracted by the presence of SO₂ in the co-capture mixture but not in the emissions mixture. The ρ values obtained for each mixture increase as the pressure increases and the temperature decreases. We did not find any density data for the CO₂+SO₂+CH₄ system in the literature.

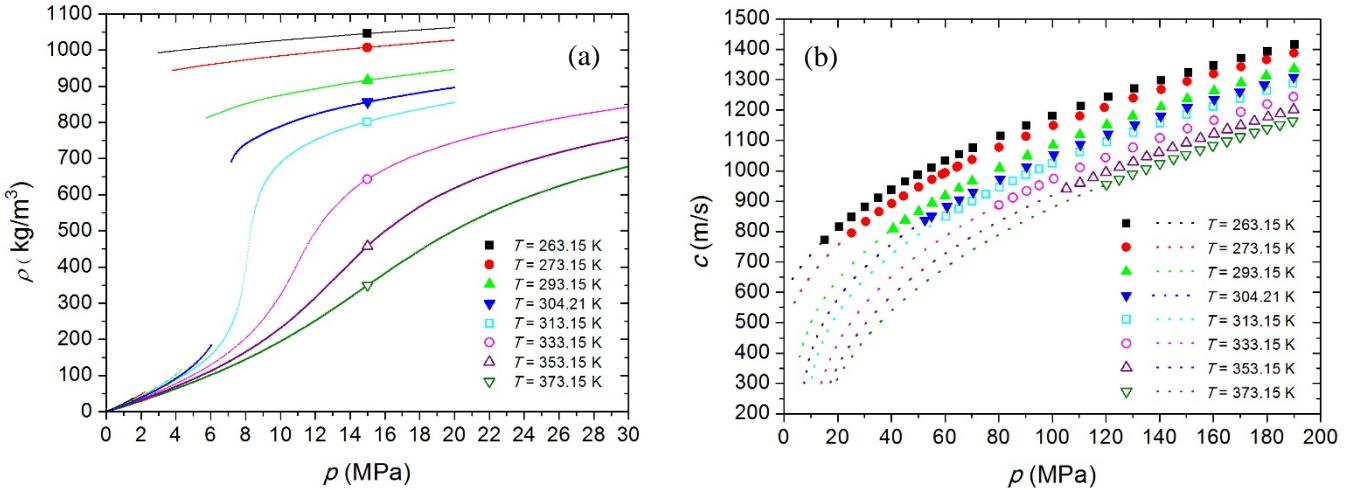

Figure 1. Experimental densities, ρ (a), and experimental (symbol) and extrapolated (dotted line) speeds of sound, c (b), for Mixtures 1 and 2, respectively, versus pressure, p , at the nominal temperatures T .

From the experimental data, we obtained p_{dew} , p_{bubble} , ρ_V , and ρ_L values for Mixture 1 at 263.13, 273.16, 293.15 and 304.21 K and for Mixture 3 at 263.16, 273.15 and 293.15 K. The results are listed in Table S3 and presented in Figure 2. The remaining isotherms were supercritical with continuous lines and a slope that reaches a maximum at the critical conditions of the mixture and diminishes as the temperature increases. No VLE data on this system were found in the literature.

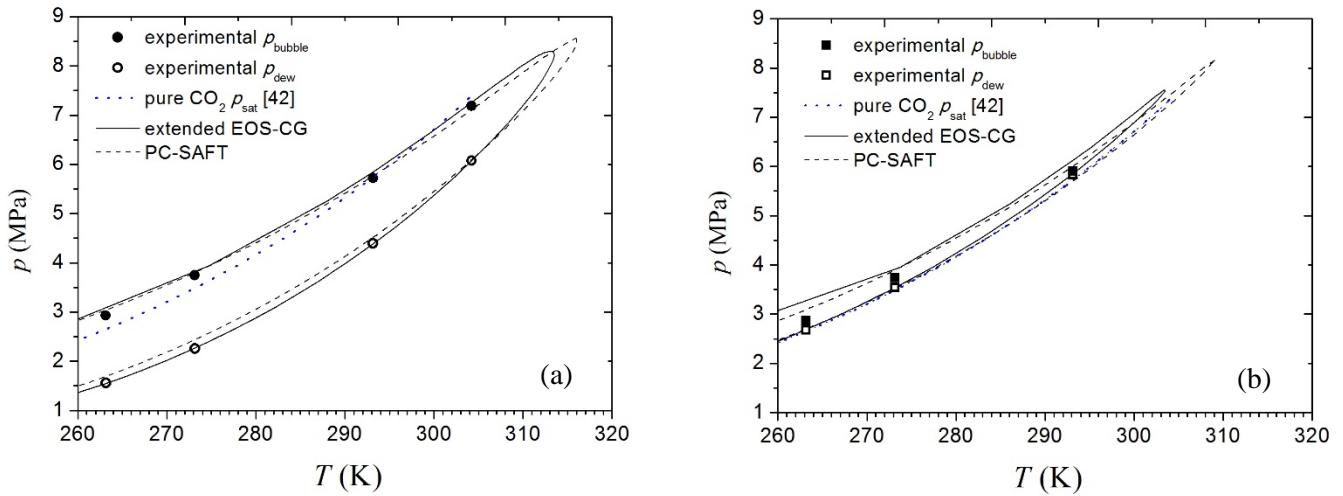

Figure 2. VLE for the $\text{CO}_2+\text{SO}_2+\text{CH}_4$ system and for pure CO_2 . Dew and bubble pressures versus temperature for Mixtures 1 (a) and 3 (b). PC-SAFT EoS was applied with parameters from Table S11.

In a previous work [15], we determined that mixtures with greater than 90 mol% CO₂ did not show proper sound signals at 5 MHz, and to obtain proper signals the mixtures were doped with CH₃OH. We studied the CO₂+SO₂ mixture with $x_{\text{SO}_2} = 0.1032$ over the same T and p ranges used in this work and we showed that the difference in c between the mixture doped with 0.8 mol% CH₃OH and the undoped mixture was small in the experimental results (0.17% on average) and was negligible in the modeling results. Afterwards, we used this method for the experimental acoustic investigation of the CO₂+SO₂ system over wide ranges of composition, T and p [8,9]. In relation to the opacity, CO₂+SO₂+CH₄ mixtures showed an analogous behavior, and they were doped as well. To evaluate the effect of CH₃OH used as a dopant we selected the co-capture mixture, given that a higher concentration of SO₂ provides better sound signals in wider ranges of pressure at each temperature [8,9,15]. The procedure was the same as in Ref. [15]. We prepared two CO₂+SO₂+CH₄ mixtures with co-capture compositions and two other mixtures with co-capture compositions doped with 0.79 mol% CH₃OH (values for x_i and $u(x_i)$ are provided in Table S4). The value of c was measured in both types of mixtures at 263, 293 and 313 K and over a range of pressures from 84.91 to 190.29 MPa (undoped) and from 15.20 to 191.12 MPa (doped), with each isotherm determined at least twice (Table S5). Comparison of the results for both types of mixtures in the common pressure ranges permitted us to quantify the effect of CH₃OH on the experimental values of c . The overall mean relative deviation, \overline{MRD}_c , was only 0.13%, which is lower than the value obtained in the study on CO₂+SO₂ [15].

We determined 8 $pctx_{\text{CO}_2}$ isotherms per mixture for Mixtures 2 (co-capture) and 4 (emissions), both CH₃OH-doped (Table 2), at the same nominal temperatures for which the density was determined and at pressures of up to 190 MPa (Table S6, Figure 1, Figure S3). A polynomial model was fitted to the experimental values of c for each composition and T [15]:

$$(p - p^\#) = \sum_{i=1}^3 a_i (c - c^\#)^i \quad (3)$$

where $p^\#$ is an appropriate reference pressure for each isotherm and $c^\#$ is the speed of sound at $p = p^\#$. Table S7 shows the coefficients for equation (3), the values of $p^\#$, and the mean relative deviations, MRD_c (%), between the experimental and fitted values. $\overline{MRD_c}$ was 0.007%, which is lower than $u(c)$ for the experimental data. The values of c were extrapolated to the low-pressure region where, in spite of the doping, no sound signal was obtained but where values of this property are important for CCS and CO₂-EOR technologies. For this purpose, polynomial (3) and the coefficients from Table S7 were used, and the extrapolated values are reported in Table S8. These data were validated with the extended EOS-CG, as explained in the next section.

The variation in c in the mixtures with composition, T and p was similar to that observed for density. We did not find any data in the literature on the speed of sound in CO₂+SO₂+CH₄ and CO₂+CH₃OH+SO₂+CH₄ systems.

3.2 Comparison of experimental and modeling data

CCS technology involves a wide range of fluid conditions that require the use of a predictive tool, such as an EoS, to calculate the necessary properties [7,43-45]. The original EOS-CG mixture model [16], based on the GERG EoS [46], is an EoS mainly developed for application to humid gases, combustion gases and CO₂-rich mixtures of interest for CCS. The original EOS-CG does not include SO₂ and CH₄. In this work, we use both an unpublished extended EOS-CG, which includes the binary models for the CO₂+SO₂ and CO₂+CH₄ subsystems, and the PC-SAFT EoS [18]. We evaluated these EoSs by comparing the values obtained from them with our experimental data. The differences are given as the mean relative deviation, MRD_X . The CH₃OH-doped mixtures

used for c measurements were modeled as pseudoternary $\text{CO}_2+\text{SO}_2+\text{CH}_4$ mixtures, with the mole fractions of CH_3OH added to those of CO_2 .

The extended EOS-CG was applied as implemented in available TREND 3.0 software (Thermodynamic Reference & Engineering Data) [17]. An extended version of EOS-CG that covers additional minor components is programmed in this software. The binary models for the CO_2+SO_2 and CO_2+CH_4 subsystems were developed at Ruhr University Bochum and are currently unpublished. For the CO_2 , SO_2 and CH_4 pure fluids, the model uses the Span and Wagner EoS [42], the Gao et al. EoS [47] and the Setzmann and Wagner EoS [48], respectively. The MRD_X values for the ternary mixtures are shown in Tables S9 and S10. With respect to ρ (Table S9 and Figure S4), the MRD_ρ values did not show a clear trend with composition, but they increased at temperatures near the critical temperatures of the mixtures. Regarding the VLE (Table S10 and Figure 2), the deviations did not show clear trends, except for p_{bubble} , which is much better reproduced for Mixture 1 (co-capture) than for Mixture 3 (emissions). Finally, for c (Table S9, Figure S5), we did not find remarkable trends with composition, but the values decreased with increasing T in the emissions mixture. For the extrapolated values (Table S9), the deviations are higher for Mixture 3 than for Mixture 1, except at 263 and 313 K. This comparison served to validate the extrapolated data.

The calculations with the PC-SAFT EoS were performed using VLXE software [49]. The methodology was described previously [15]. The pure compound parameters; the binary interaction parameters, k_{ij} ; and the Δv_c values are listed in Table S11. The CO_2-SO_2 and CO_2-CH_4 k_{ij} values are equal to those used in previous works [8,9,15,20]. We set SO_2-CH_4 k_{ij} to zero because a binary interaction parameter obtained from fitting our experimental data did not significantly modify the results. The comparison between the calculated and experimental values

determined in this work is shown in Tables S9 and S10 and Figures 2, S4 and S5. The MRD_ρ values near the critical temperature, T_c , and at supercritical T values were higher than those at subcritical T values, resulting in higher deviations than those for EOS-CG at all isotherms. There was no clear trend with the composition. Regarding the VLE, the deviations in the predictions of ρ_V and ρ_L did not show trends with composition, but the highest deviations in p_{dew} and p_{bubble} were obtained for the co-capture mixture and the emissions mixture, respectively. Relative to the experimental results, MRD_c decreased with increasing T and was slightly higher for Mixture 3 than for Mixture 1. For the extrapolated results, the lowest values of MRD_c were found at 263 K and 273 K for the two mixtures.

In addition, we evaluated the predictive capability of PC-SAFT using different parameters found in the literature [50-52] by comparing the predicted data with our experimental data, and the MRD_X values obtained are listed in Table S12. From these results, the overall conclusion is that PC-SAFT, with the parameters from the first two rows of Table S12, better reproduces our experimental values than PC-SAFT with the rest of the parameters found in the literature [51,52].

Table 3 collects the global average values, $\overline{\overline{MRD}_X}$, of the mean relative deviations obtained for each property with both EoSs.

EoS	$\overline{\overline{MRD}_\rho}$ (%)	$\overline{\overline{MRD}_{c,\text{exp}}}$ (%)	$\overline{\overline{MRD}_{c,\text{ext}}}$ (%)	$\overline{\overline{MRD}_{p_{\text{dew}}}}$ (%)	$\overline{\overline{MRD}_{p_{\text{bubble}}}}$ (%)	$\overline{\overline{MRD}_{\rho_V}}$ (%)	$\overline{\overline{MRD}_{\rho_L}}$ (%)
extended EOS-CG	0.46	0.32	0.42	0.22	3.16	0.58	0.16

Table 3. Global average values, $\overline{\overline{MRD}_X}$, of the mean relative deviations. Subscripts exp and ext mean experimental and extrapolated, respectively.

3.3 Influence of SO₂ in the presence of CH₄ on transport, injection and storage of CCS technology.

The presence of impurities in anthropogenic CO₂ greatly affects the volumetric, VLE and acoustic properties, as demonstrated in Section 3.1. In this section, several technical parameters related to transport, injection and storage in CCS technology will be discussed to quantify the effect of both the presence and the concentrations of SO₂ and CH₄ in the managed fluid. For this purpose, the technical parameters for CO₂+SO₂+CH₄ Mixtures 1 (co-capture) and 3 (emissions) were compared with those calculated for pure CO₂ [42] and those for both binary mixtures, CO₂+SO₂ and CO₂+CH₄, with similar contents of SO₂ and CH₄ as the ternary mixtures, taken from Ref. [8,9,20,21].

The transport parameters were the minimum operational pressure, p_{\min} ; the pressure and density profiles along the pipeline, $p(d)$, where d is the distance; and the inner diameter of the pipeline, D , and were calculated at temperatures from 263 to 304 K. Regarding injection and storage, normalized parameters, X/X_0 , were evaluated, where X is the value corresponding to the mixtures and X_0 corresponds to pure CO₂. The parameters were the storage capacity, M ; the rising velocity of the plume inside deep saline aquifers, v ; and the permeation flux, \dot{M} and were evaluated at temperatures from 313 to 373 and pressures $p \geq 7$ MPa. All of the above parameters and other required values, such as the Reynolds number, friction factor, pressure drop per meter and normalized floatability in saline aquifers, were calculated using the recommended equations [21,53,54], as shown in Table S13. In these equations, the values for ρ were those from Table S1 for ternary mixtures and values from the literature [8,9,20,21] for binary mixtures; ρ_0 data were taken from the literature [42]. The brine densities, ρ_{Br} , of the saline aquifers in Table 1 were estimated as in Ref. [9] using the salinity, temperature and pressure inside the reservoir.

The viscosity values for pure CO₂, η_0 , were calculated using REFPROP 9.1 software [55]. We did not find experimental viscosity data, η , in the literature for the binary and ternary mixtures used in this work, so we used calculated values for the binary mixtures using an improved extended corresponding states method to estimate the viscosity [56], as implemented in REFPROP 9.1 [55], similar to previous works [8,9,20,21]. However, this software does not allow us to obtain η for ternary mixtures; thus, we calculated these values at pressures ≥ 7 MPa using the equation from Grunberg and Nissan [57] applied to the ternary mixture according to the formulation of Shu et al. [58]:

$$\ln\eta = \sum_{i=1}^n x_i \ln\eta_i + \sum_i^n \sum_{j>i}^n x_i x_j A_{ij} + \sum_i^n \sum_{j>i}^n \sum_{k>j}^n x_i x_j x_k A_{ijk} \quad (4)$$

where η is the viscosity ($\mu\text{Pa}\cdot\text{s}$) of Mixture 1 or 3; η_i is the viscosity ($\mu\text{Pa}\cdot\text{s}$) of the pure components; x_i , x_j and x_k are the mole fractions of the i , j and k components, respectively; A_{ij} is a binary interaction parameter; A_{ijk} is a ternary interaction parameter; and n is the number of components in the mixture. The Grunberg and Nissan equation is widely used in the literature for water-free liquid mixtures [59]. A_{ij} for the SO₂-CH₄ interaction and A_{ijk} were set to zero because of the small mole fractions of these compounds in the ternary mixtures. The values of A_{ij} for CO₂-SO₂ and CO₂-CH₄ binary interactions at each temperature were adjusted from the viscosity data of the corresponding binary mixtures obtained from REFPROP 9.1 [55] and are shown in Table S14 together with the mean relative deviations, MRD_η (%), between the REFPROP 9.1 [55] values and those obtained from equation (4).

3.3.1 Influence of SO₂ in the presence of CH₄ on transport.

Minimum operational pressure, p_{\min} . The managed fluid must be transported in a dense or supercritical phase, given that biphasic flow reduces the efficiency of the transport and can damage

the facilities by cavitation and turbulence [39]. Therefore, the minimum operational pressure is determined by the fluid p_{bubble} (plus a margin for safety). The presence of a condensable impurity such as SO₂ decreases the p_{bubble} value of the mixture with respect to the saturation pressure, p_{sat} , of pure CO₂ at each T , while in the presence of a noncondensable impurity, such as CH₄, the p_{bubble} value increases (Table S15). These opposite effects compete in the studied ternary Mixtures 1 (co-capture) and 3 (emissions). As a result, the p_{bubble} values of Mixture 3 at all studied subcritical temperatures and those of Mixture 1 at 263.15 and 273.15 K were higher than the respective pure CO₂ p_{sat} values. For Mixture 1, p_{bubble} is equal to p_{sat} of CO₂ at 293.15, and at 304.21 K (pure CO₂ T_c) [56], p_{bubble} is lower than the critical pressure, p_c , for the pure fluid, which is 7.383 MPa [60] (Table S15). A higher p_{bubble} value has a negative effect on transport since it requires the use of higher minimum operational pressures; however, lower p_{bubble} values are favorable.

Pressure and density drops along the pipeline and pipeline inner diameter, D. Figure S6 presents the pressure and density profiles along the pipeline for the studied Mixtures 1 (co-capture) and 3 (emissions) compared with those of pure CO₂ at all studied transport temperatures. A pipeline inner diameter of 0.508 m (20 inch), a mass flow of 317 kg/s (10 Mt/year), a roughness height of the pipeline of 4×10^{-5} m (0.00015 ft) and an inlet pressure of 20.00 MPa were considered. Figure S7 shows similar representations at 293.15 K along with profiles for the binary CO₂+SO₂ (4.68 mol% or 0.69 mol%) [8] and CO₂+CH₄ (1.91 mol%) [21] mixtures. Figure S8 shows the pipeline inner diameter, D , as a function of the mass flow, m , for the studied ternary mixtures compared with pure CO₂ at several values of T and p , and Figure S9 presents D versus m for the ternary mixtures, the binary mixtures and pure CO₂ at 293.15 K and 14 MPa. Noncondensable CH₄ increases the pressure and density drops, as well as the needed inner diameter for a given flow,

with respect to those of pure CO₂, while condensable SO₂ decreases all three values due to the influence of these impurities on the density and the viscosity of the mixture. These opposite effects compete in the ternary mixtures. For Mixture 1 (4.72 mol% of SO₂ and 1.85 mol% of CH₄), the effect of SO₂ predominates, so the pressure and density decrease more slowly than for pure CO₂, and the needed inner diameter is smaller. However, for Mixture 3 (0.09 mol% of SO₂ and 1.54 mol% of CH₄), the effect of CH₄ is the most important, so the pressure and density drop faster than those of pure CO₂, and the pipeline inner diameter must be larger. Hence, the co-capture mixture presents favorable properties for transport with respect to pure CO₂, while the emissions mixture is unfavorable.

3.3.2 Influence of SO₂ in the presence of CH₄ on injection and storage.

Normalized storage capacity, M/M_0 . The reservoir temperature and pressure and the presence of impurities in the injected stream affect the density of the fluid and thus the amount of fluid that can be stored. When the impurity T_c is higher than the CO₂ T_c , as is the case for SO₂, the $M/M_0 - p$ isotherm of the CO₂+SO₂ mixture exhibits a maximum [9,61], whereas if the impurities are noncondensable gases, such as CH₄, a minimum appears in the isotherm [19,21]. The $M/M_0 - p$ isotherms for the co-capture mixture in Figure S10 show maxima, with values that decrease and positions that shift to higher pressures with increasing temperature. However, the isotherms for the emissions mixture show minima with increasing values and positions that shift to higher pressures when T increases. Thus, SO₂ compensates for the CH₄ effect in the co-capture mixture, although values of $M/M_0 > 1$ are obtained only at 313.15 K and 7 MPa < p < 10 MPa and at 333.15 K and 9 MPa < p < 14 MPa. However, the SO₂ concentration in the emissions mixture does not completely compensate for the negative effect of CH₄; thus, the values of this parameter are lower than 1 along the whole range of studied conditions. At high pressures, the influences of

T and p diminish, and the emissions composition leads to higher values of M in comparison to the co-capture composition.

In terms of the quantity of the stored fluid in the seven actual reservoirs shown in Table 1, the presence of 1.91 mol% CH₄ leads to reductions between 3 and 6% (Figure 3). These reductions can be overcome by coinjecting 4.72 mol% SO₂ (co-capture mixture) in Sleipner (1000 m depth) but not in the other reservoirs. It can also be observed that the co-capture mixture is the least favorable for storage in the three deeper sites.

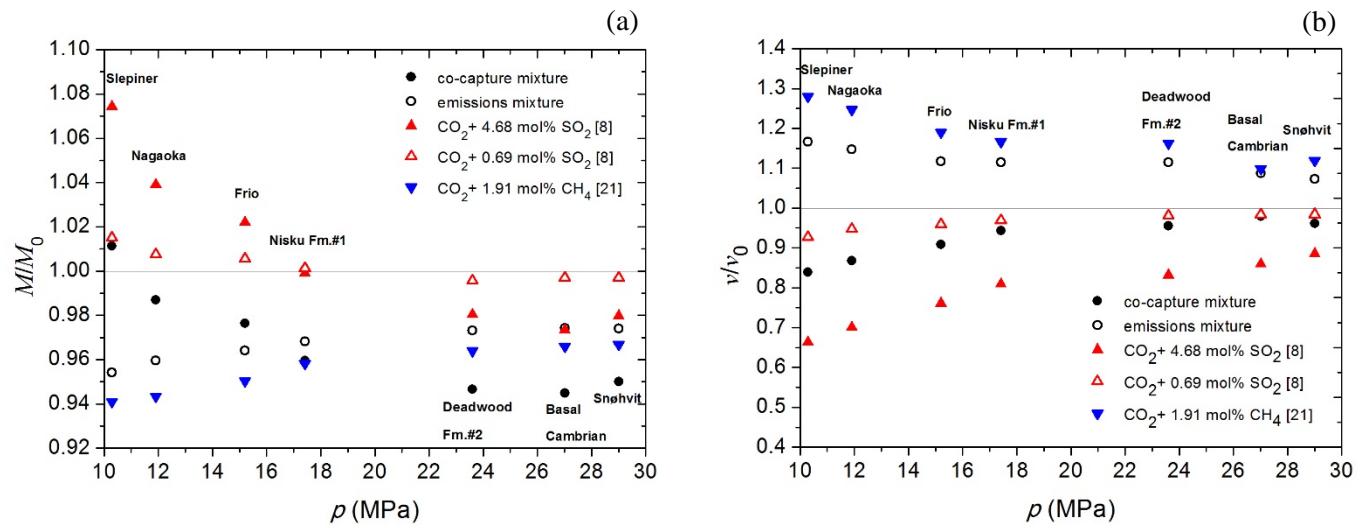

Figure 3. Normalized storage capacity, M/M_0 (a), and normalized rising velocity in saline aquifers, v/v_0 (b) for different mixtures under the reservoir conditions presented in Table 1 [22-28].

Normalized rising velocity in saline aquifers, v/v_0 . CO₂+SO₂ mixtures with x_{SO_2} values similar to those for Mixtures 1 and 3 result in minima in the $v/v_0 - p$ isotherms and values of $v/v_0 < 1$ over the studied T and p ranges [9], while CO₂+CH₄ mixtures with 1.91 mol% CH₄ lead to maxima and values of $v/v_0 > 1$ [19,21]. Figure S10 shows that 4.72 mol% SO₂ overcomes the effect of 1.85 mol% CH₄ in the co-capture mixture, giving minima in the $v/v_0 - p$ isotherms and values of $v/v_0 < 1$, corresponding to an increasing solvent effect by favoring the CO₂-brine contact.

However, 0.09 mol% SO₂ is not sufficient to completely compensate for the negative effect on this parameter due to 1.54 mol% CH₄ in the emissions mixture (Figure S10).

In the reservoirs represented in Figure 3, the presence of methane leads to values of $\nu > \nu_0$, except for the co-capture mixture, in which the effect of this impurity is overcome by the presence of SO₂. The presence of the studied impurities in shallow reservoirs leads to differences in ν/ν_0 of up to 61% (Figure 3), and these differences become less significant in deep locations.

Normalized permeation flux, \dot{M}/\dot{M}_0 . Most values of the $\dot{M}/\dot{M}_0 - p$ isotherms (Figure S10) are higher, and thus better, than those of $M/M_0 - p$ at the same values of p and T , which means that the viscosity of Mixtures 1 and 3 favors their permeation flux under the studied conditions. Thus, Mixture 1 shows values of $\dot{M}/\dot{M}_0 > 1$ at temperatures of 313.15 K and 333.15 K and pressures of 9 MPa $\leq p \leq$ 17 MPa, while Mixture 3 has values of $\dot{M}/\dot{M}_0 > 1$ at 313.15 K and $p > \approx 10.5$ MPa and at 333.15 K and $p > \approx 18$ MPa; $\dot{M}/\dot{M}_0 \cong 1$ in deeper reservoirs.

Figure S11 shows that almost all of the systems studied in this work show better permeation flux values than those for pure CO₂ when injected into the four shallower reservoirs, while none of the mixtures are favorable in the deepest reservoir, Snøhvit. In the case of Deadwood and Basal Cambrian, only the SO₂-free mixture and the emissions mixture have improved permeation flux values relative to pure CO₂.

4. CONCLUSIONS

From our experimental thermodynamic study of CO₂+4.72 mol% SO₂+1.85 mol% CH₄ (co-capture mixture) and CO₂+0.09 mol% SO₂+1.54 mol% CH₄ (emissions mixture) we determined the influence of the simultaneous presence of a condensable compound, SO₂, and a non-condensable, CH₄, in the studied CO₂-rich mixtures within the operational ranges of technologies as CCS and CO₂-EOR. We conclude that the density decreasing effect of CH₄ is counteracted by

the presence of SO₂ in the co-capture mixture, leading to density values higher than those of pure CO₂, but not in the emissions mixture. CH₄ increases the bubble pressure above the pure CO₂ p_{sat} in both mixtures, despite the contrary effect of SO₂. In relation to dew limits, the SO₂ (increasing) and CH₄ (decreasing) effects predominate in the co-capture mixture and in the emissions mixture, respectively. The speed of sound is only slightly affected by the presence and the amount of the studied minority compounds.

An unpublished extended EOS-CG, as implemented in available TREND 3.0 software, and the PC-SAFT EoS were validated for the studied systems and conditions. We conclude that the extended EOS-CG reproduces our experimental data much better than the PC-SAFT with the parameters listed in Table S11. Moreover, predictions by the PC-SAFT using the parameters listed in Table S11 and those in the second row of Table S12 were better than the predictions obtained using other parameters from the literature.

We assessed the convenience of the transport, injection and storage of CO₂ containing SO₂ and CH₄ at the concentrations used in this study, as well as the feasibility of CO₂/SO₂ co-capture and storage in presence of CH₄. We conclude that the co-capture mixture, contrary to the emissions mixture, presents favorable properties with respect to pure CO₂ in relation to the required pipeline diameter and pressure and density drops during transport. Only the co-capture mixture at 304.21 K allows a lower minimum operational pressure than that used for pure CO₂. Furthermore, only the co-capture mixture injected in Sleipner would improve the storage efficiency relative to that of pure CO₂; however, this mixture decreases the rising velocity in all the studied reservoirs, thus improving their safety. In addition, this mixture favors the permeation flux in the four shallower studied reservoirs.

We conclude that the effect of SO₂ in the co-capture mixture overcomes the negative impact of CH₄ in most of the studied aspects –but the chemical reactivity was not taken into consideration— even though the global conclusions must be derived from the balance of all components involved in the technologies.

ACKNOWLEDGMENTS

This work was supported by the Ministry of Economy and Competitiveness of Spain [ENE2013-44336-R], the Government of Aragon and European Social Fund [T46_17R], and the University of Zaragoza. Authors would like to thank Dr. Roland Span for making the TREND 3.0 software available and Dr. Luis Rández for assistance with computing, and they also acknowledge the use of Servicio General de Apoyo a la Investigación-SAI, Universidad de Zaragoza.

SUPPLEMENTARY MATERIAL

Additional tables and figures regarding the experimental data, EoS modeling and transport, injection and storage parameters are presented.

NOMENCLATURE

a_i	Coefficients in polynomials fitted to the speed of sound values.
A_{ij}	Binary interaction parameter for viscosity calculations.
A_{ijk}	Ternary interaction parameter for viscosity calculations.
c	Speed of sound.
CCS	Carbon Capture and Storage.
d	Distance traveled by the stream along a pipeline.
D	Inner diameter of the pipeline.
M/M_0	Normalized storage capacity of a reservoir.

\dot{M}/\dot{M}_0	Normalized permeation flux of the plume in a reservoir.
MRD_X	Mean relative deviation for property X .
$\overline{\overline{MRD}_X}$	Global average values of the mean relative deviation for a property X .
p	Pressure
$p^\#$	Reference pressure in polynomials fitted to the speed of sound values.
p_{bubble}	Bubble pressure.
p_{dew}	Dew pressure.
p_{sat}	Saturation pressure.
T	Temperature.
$u(X)$	Combined uncertainty for property X .
v/v_0	Normalized rising velocity of the plume in saline aquifers.
VLE	Vapor-liquid equilibrium.
x	Mole fraction.
η	Viscosity.
ρ	Density.

Thermodynamic properties of CO₂+SO₂+CH₄ mixtures
over wide ranges of temperature and pressure. Evaluation
of CO₂/SO₂ co-capture in presence of CH₄ for CCS.

TABLE OF CONTENTS	pp.
Table S1. Experimental densities of the CO ₂ +SO ₂ +CH ₄ mixtures.	S4
Table S2. Reduced experimental densities of the CO ₂ +SO ₂ +CH ₄ mixtures.	S118
Table S3. Experimental VLE data for the CO ₂ +SO ₂ +CH ₄ mixtures.	S126
Table S4. Composition of the mixtures for the uncertainty study and for quantifying the effect of CH ₃ OH on the experimental speed of sound.	S127
Table S5. Experimental speeds of sound for the CO ₂ +SO ₂ +CH ₄ and the CO ₂ +CH ₃ OH+ SO ₂ +CH ₄ mixtures for the uncertainty study and for quantifying the effect of CH ₃ OH on the experimental speed of sound.	S128
Table S6. Experimental speeds of sound for the CO ₂ +CH ₃ OH+SO ₂ +CH ₄ mixtures.	S135
Table S7. Coefficients in the correlation of the experimental speeds of sound.	S139
Table S8. Extrapolated speeds of sound for the CO ₂ +CH ₃ OH+SO ₂ +CH ₄ mixtures.	S140
Table S9. Comparison between this work experimental density and experimental and extrapolated speed of sound data and those calculated using the extended EOS-CG or the PC-SAFT EoSs.	S152
Table S10. Comparison between this work experimental VLE data and those calculated using the extended EOS-CG or the PC-SAFT EoSs.	S153
Table S11. Parameters used in the modeling of the CO ₂ +SO ₂ +CH ₄ system with the PC-SAFT EoS.	S154
Table S12. Comparison between this work experimental data and those calculated using the PC-SAFT EoS with parameters from the literature.	S155
Table S13. Equation overview for the calculation of CCS parameters.	S156
Table S14. Coefficients for the viscosity calculations.	S157
Table S15. Bubble or saturation pressures for the studied systems.	S158
Figures S1 and S2. Experimental densities of the CO ₂ +SO ₂ +CH ₄ mixtures.	S159

Figure S3. Experimental and extrapolated speeds of sound for Mixture 4 (CO ₂ +CH ₃ OH+SO ₂ +CH ₄).	S162
Figures S4 and S5. Comparison of this work experimental density and speed of sound data to the values calculated using the extended EOS-CG and the PC-SAFT EoSs.	S163
Figures S6 and S7. Pressure and density profiles along the pipeline for the studied mixtures and pure CO ₂ .	S165
Figures S8 and S9. Pipeline inner diameter for the studied mixtures and pure CO ₂ .	S169
Figure S10. Normalized storage capacity, normalized rising velocity, and normalized permeation flux for the studied mixtures.	S172
Figure S11. Normalized permeation flux for the studied mixtures in the studied real reservoirs.	S174

Table S1. $p\rho T$ experimental data for the CO₂+SO₂+CH₄ mixtures. ($u(\rho)$: Combined standard uncertainty)

$x_{\text{CO}_2} = 0.9343; x_{\text{SO}_2} = 0.0472; x_{\text{CH}_4} = 0.0185$

$\overline{MRD_X}$ (%)	extended EOS-CG	0.46		0.32		0.42	
	PC-SAFT	1.82		4.48		3.22	

$$MRD_{X,\text{exp}}(\%) = \frac{100}{N} \sum \left| \frac{X_{\text{EoS}} - X_{\text{exp}}}{X_{\text{exp}}} \right|$$

$$MRD_{c,\text{ext}}(\%)[\text{ext-extended EOS-CG}] = \frac{100}{N} \sum \left| \frac{c_{\text{ext}} - c_{\text{EoS}}}{c_{\text{EoS}}} \right|$$

N: number of points for each composition and temperature.

$$\overline{MRD_X}_{\text{exp}}(\%) = \frac{100}{N'} \sum \left| \frac{X_{\text{EoS}} - X_{\text{exp}}}{X_{\text{exp}}} \right|$$

$$\overline{MRD_c}_{\text{ext}}(\%)[\text{ext-extended EOS-CG}] = \frac{100}{N'} \sum \left| \frac{c_{\text{ext}} - c_{\text{EoS}}}{c_{\text{EoS}}} \right|$$

N': total number of points for each property.

Table S10. Comparison between the experimental VLE data presented in this work for the CO₂+SO₂+CH₄ system and those calculated using the extended EOS-CG or PC-SAFT EoSs in terms of mean relative deviation, $MRD(\%)$, and overall mean relative deviation, $\overline{MRD}(\%)$.

Composition	EoS	$MRD_{p_{\text{dew}}}(\%)$	$MRD_{p_{\text{bubble}}}(\%)$	$MRD_{\rho_{\text{V}}}(\%)$	$MRD_{\rho_{\text{L}}}(\%)$
Mixture 1 (co-capture)	extended EOS-CG	0.27	1.88	0.58	0.20
	PC-SAFT	5.15	1.67	5.45	1.35
Mixture 3 (emissions)	extended EOS-CG	0.15	4.86	0.58	0.10
	PC-SAFT	1.14	4.57	4.93	1.17
$\overline{MRD}_X(\%)$	extended EOS-CG	0.22	3.16	0.58	0.16
	PC-SAFT	3.32	2.95	5.14	1.27

$$MRD_X(\%) = \frac{100}{N} \left| \frac{X_{\text{EoS}} - X_{\text{exp}}}{X_{\text{exp}}} \right|$$

N : number of experimental points for each composition.

$$\overline{MRD}_X(\%) = \frac{100}{N'} \sum \left| \frac{X_{\text{EoS}} - X_{\text{exp}}}{X_{\text{exp}}} \right|$$

N' : number of experimental points for each property.

Table S11. Parameters used in the modeling of the CO₂+SO₂+CH₄ system with the PC-SAFT EoS.

Pure Compound Parameter	CO ₂	SO ₂	CH ₄
<i>m/M</i> (mol/g)	0.04710 ^a	0.04466 ^a	0,062335 ^a
σ (Å)	2.7852 ^a	2.6826 ^a	3.7039 ^a
ε (K)	169.21 ^a	205.35 ^a	150.03 ^a
Δv_c (cm ³ /g)	0.02 ^b	0.01 ^c	----
Binary interaction parameters: CO ₂ –SO ₂ : $k_{ij} = 0.03^d$; CO ₂ –CH ₄ : $k_{ij} = 0.07^b$			

^a Ref. [18]; ^b Ref. [20]; ^c Ref. [9]; ^d Ref. [50].

Table S12. Comparison between the experimental $p\!pT$, $p\!cT$ and VLE data presented in this work for the CO₂+SO₂+CH₄ system and those calculated using the PC-SAFT EoS with parameters from the literature [20,50-52] in terms of overall mean relative deviation, \overline{MRD}_X (%). The doped mixtures for c measurements were modeled as pseudobinary mixtures in which the mole fraction of CO₂ was $x_{CO_2} = 1 - x_{SO_2} - x_{CH_4}$.

PC-SAFT parameters	\overline{MRD}_ρ (%)	$\overline{MRD}_{p_{dew}}$ (%)	$\overline{MRD}_{p_{bubble}}$ (%)	\overline{MRD}_{ρ_V} (%)	\overline{MRD}_{ρ_L} (%)	\overline{MRD}_c (%)

Pure compound parameters from Ref. [52]						

$$\overline{MRD}_X(\%)[\text{exp-EoS}] = \frac{100}{N'} \sum \left| \frac{X_{\text{EoS}} - X_{\text{exp}}}{X_{\text{exp}}} \right| \quad N': \text{total number of experimental points for each property.}$$

Table S13. Equation overview for the calculation of transport parameters in pipeline design and operation and for the calculation of injection and storage parameters [21,53,54].

	Equations	Symbols
Mass flow	$m = \rho \times v \times A$	m = mass flow (kg/s); ρ = fluid density (kg/m ³); v = fluid velocity (m/s); A = pipeline inner section (m ²).
Pipeline inner diameter	$D = \left(\frac{4 \times m}{v \times \pi \times \rho} \right)^{1/2}$ $= \left[\frac{8 \times f \times m^2}{\rho \times \pi^2 \times \frac{\Delta p}{d}} \right]^{1/5}$	D = inner diameter (m); m = mass flow (kg/s); v = fluid velocity (m/s); ρ = fluid density (kg/m ³); f = Darcy-Weisbach friction factor; $(\Delta p/d)$ = pressure drop per metre (Pa/m).
Reynolds number	$Re = \frac{\rho \times v \times D}{\eta} = \frac{4 \times m}{\pi \times \eta \times D}$	Re = Reynolds number; ρ = fluid density (kg/m ³); v = fluid velocity (m/s); D = inner diameter (m); η = fluid viscosity (Pa.s); m = mass flow (kg/s).
Darcy-Weisbach friction factor	$f = \frac{1.325}{\left[\ln \left[\frac{e}{3.7 \times D} + \frac{5.74}{Re^{0.9}} \right] \right]^2}$	f = Darcy-Weisbach friction factor; e = roughness height (m); D = inner diameter (m); Re = Reynolds number.
Pressure drop per meter	$\frac{\Delta p}{d} = \frac{8 \times f \times m^2}{\rho \times \pi^2 \times D^5}$	$(\Delta p/d)$ = pressure drop per metre (Pa/m); m = mass flow (kg/s); ρ = fluid density (kg/m ³); f = Darcy-Weisbach friction factor; D = inner diameter (m).
Normalized storage capacity	$\frac{M}{M_0} = \frac{\rho}{\rho_0 \left[1 + \sum_i \frac{m_i}{m_0} \right]}$	M/M_0 = normalized storage capacity; ρ = mixture density (kg/m ³); ρ_0 = pure CO ₂ density (kg/m ³); m_i : mass of impurity in the mixture; m_0 = mass of pure CO ₂ in the mixture
Normalized flotability in saline aquifers	$\frac{F}{F_0} = \frac{(\rho_{Br} - \rho)}{(\rho_{Br} - \rho_0)}$	F/F_0 = normalized rising velocity; ρ_{Br} = brine density (kg/m ³); ρ = mixture density (kg/m ³); ρ_0 = pure CO ₂ density (kg/m ³)
Normalized rising velocity in saline aquifers	$\frac{v}{v_0} = \frac{F(\rho_0 \eta_0)}{F_0(\rho \eta)}$	v/v_0 = normalized rising velocity; ρ_{Br} = brine density (kg/m ³); ρ = mixture density (kg/m ³); ρ_0 = pure CO ₂ density (kg/m ³); η_0 = pure CO ₂ viscosity (μPa.s); η = mixture viscosity (μPa.s)
Normalized permeation flux	$\frac{\dot{M}}{\dot{M}_0} = \frac{\rho \left(\frac{\eta_0}{\eta} \right)}{\rho_0 \left[1 + \sum_i \left(\frac{m_i}{m_0} \right) \right]}$	\dot{M}/\dot{M}_0 = normalized permeation flux; ρ = mixture density (kg/m ³); ρ_0 = pure CO ₂ density (kg/m ³); η_0 = pure CO ₂ viscosity (μPa.s); η = mixture viscosity (μPa.s); m_i : mass of impurity in the mixture; m_0 = mass of pure CO ₂ in the mixture

Table S14. Values of A_{ij} for CO₂-SO₂ and CO₂-CH₄ binary interactions in equation (4) at temperatures T , as well as the mean relative deviations.

304.21	7.185		6.689	7.182		

^a This work; ^b Ref. [8]; ^c Ref. [21]; ^d Ref. [42].

Figure S1. Experimental densities, ρ , for Mixture 3 (emissions) versus pressure, p , at the nominal temperatures T .

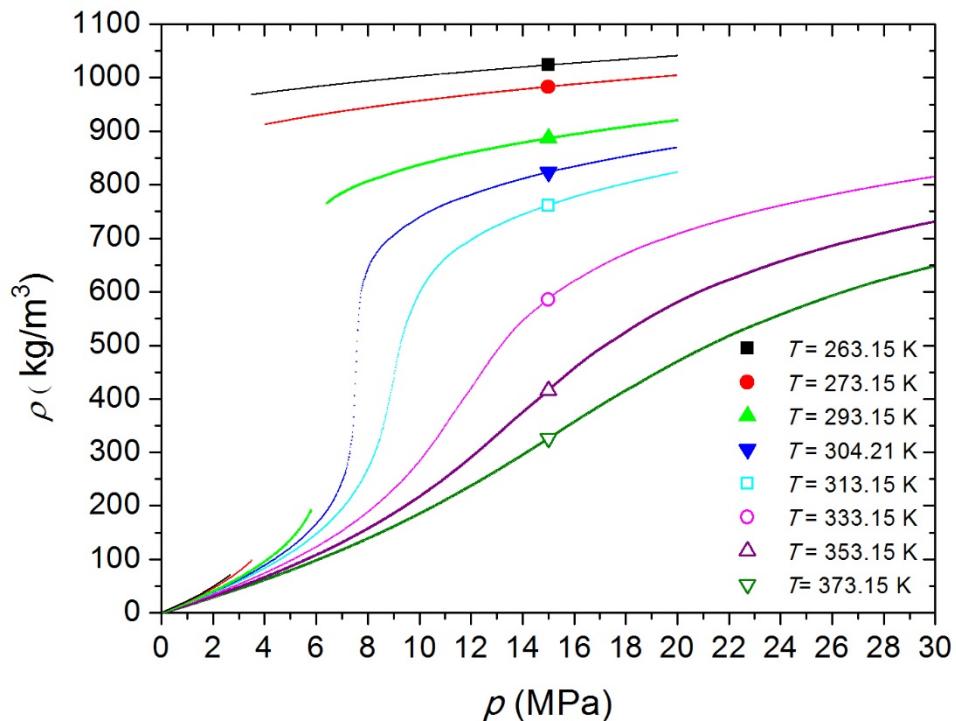

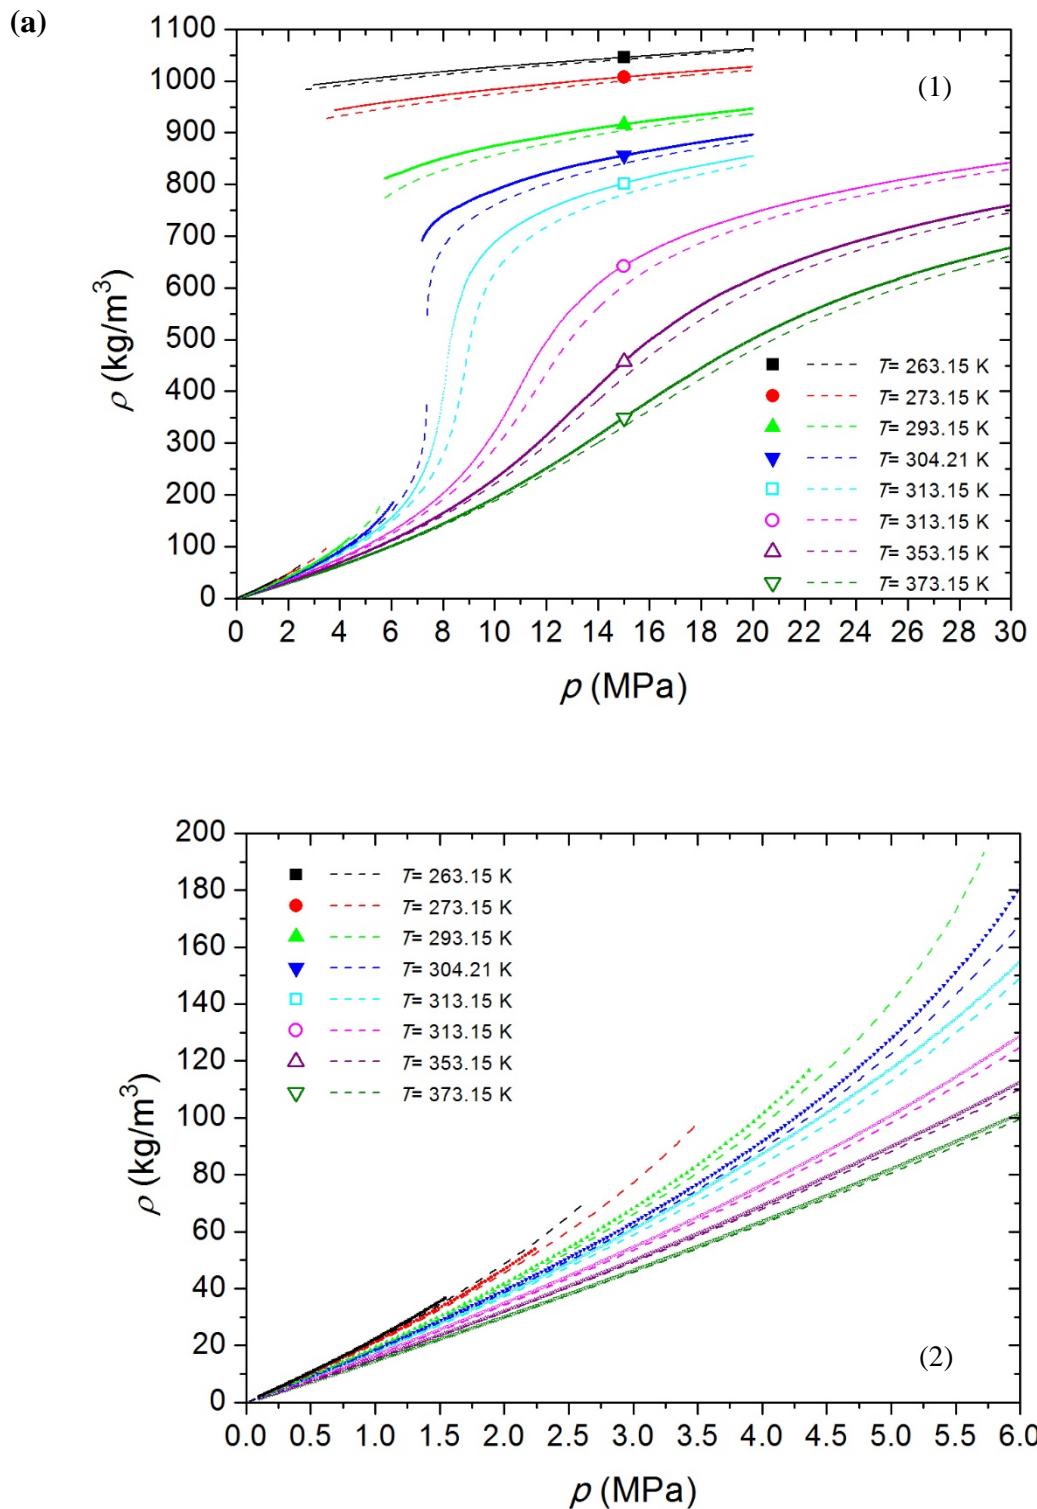

Figure S2. Experimental densities, ρ , of Mixture 1 (co-capture) **(a)** and Mixture 3 (emissions) **(b)** (symbols), and pure CO₂ [42] (dashed line) versus pressure, p , at the nominal temperatures, T . (1) Whole studied range of pressures. (2) Enlargement of the gas phase region.

(b)

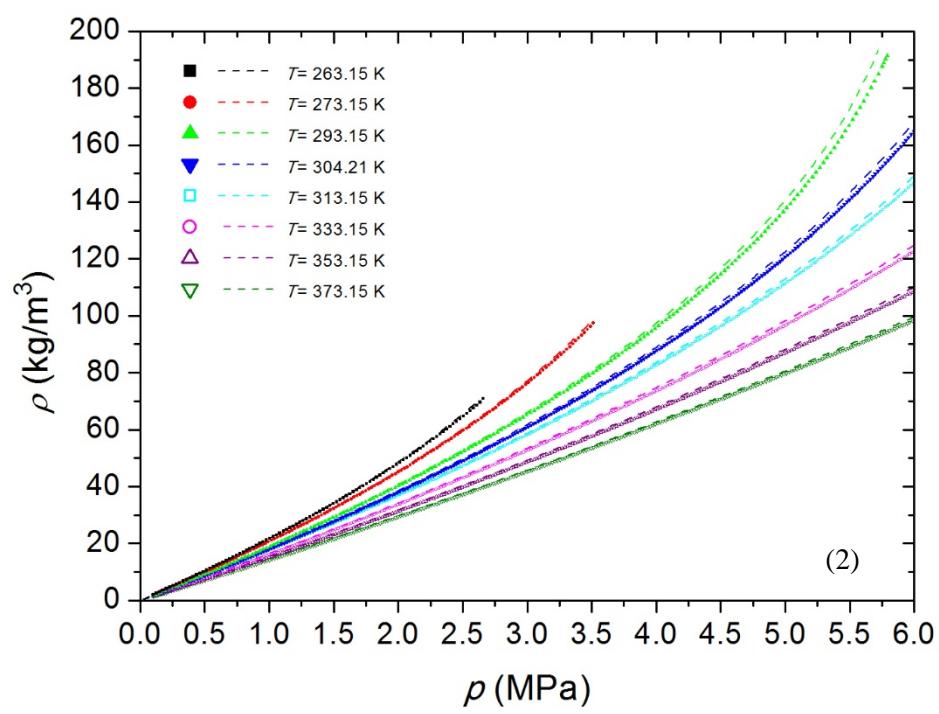

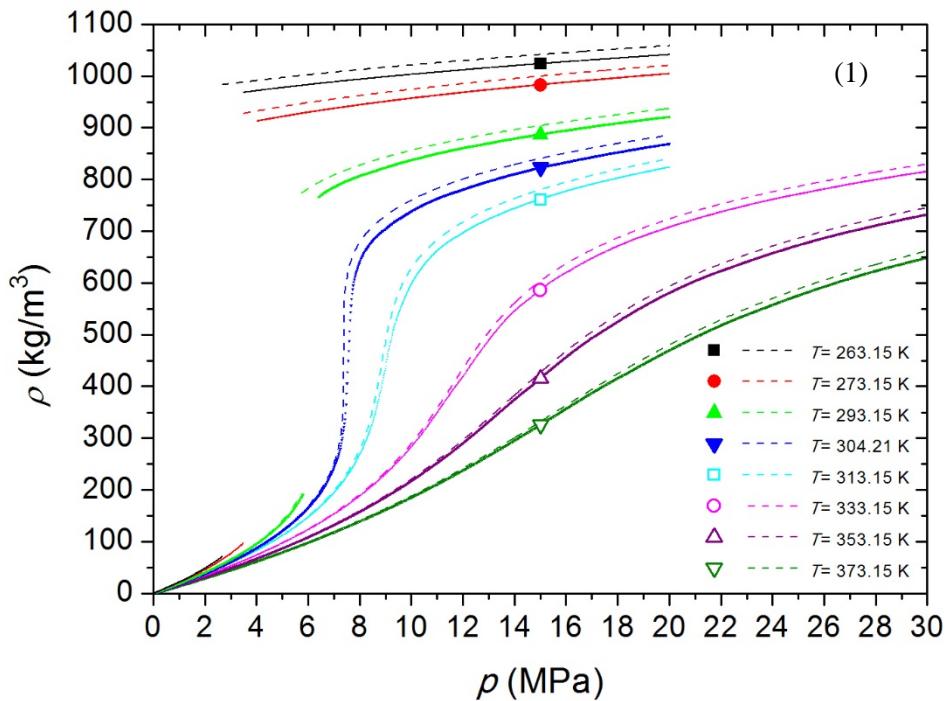

Figure S3. Experimental speed of sound, c , for Mixture 4 (emissions) versus pressure, p , at the nominal temperatures T .

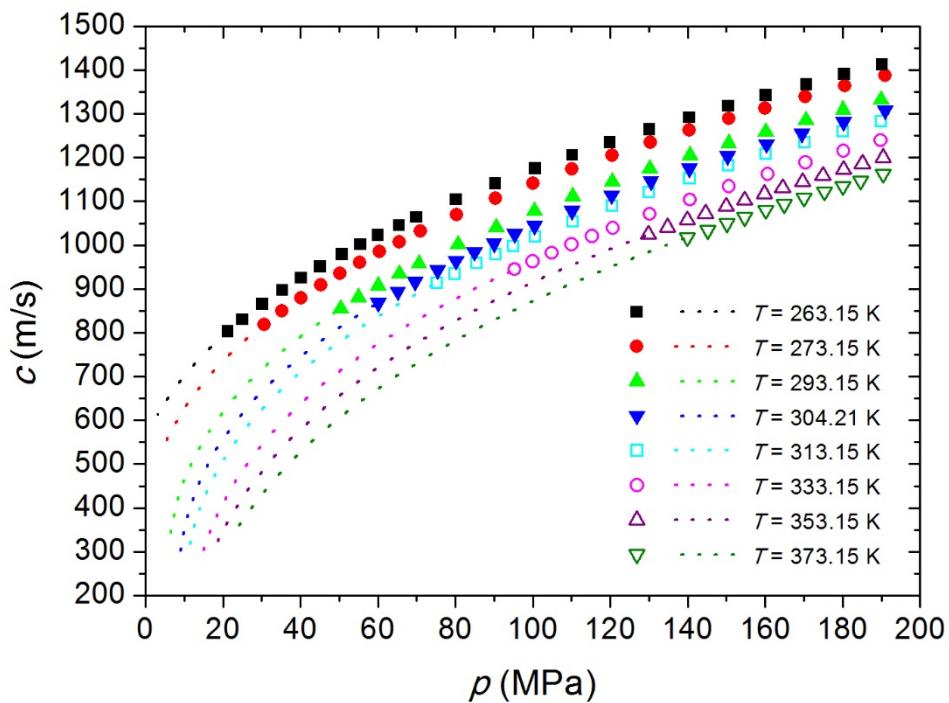

Figure S4. Relative deviations between the experimental densities, ρ_{exp} , in this work and the values calculated from the extended EOS-CG and PC-SAFT EoS, ρ_{EoS} , for Mixtures 1 (co-capture) (a) and 3 (emissions) (b) at the nominal temperatures, T .

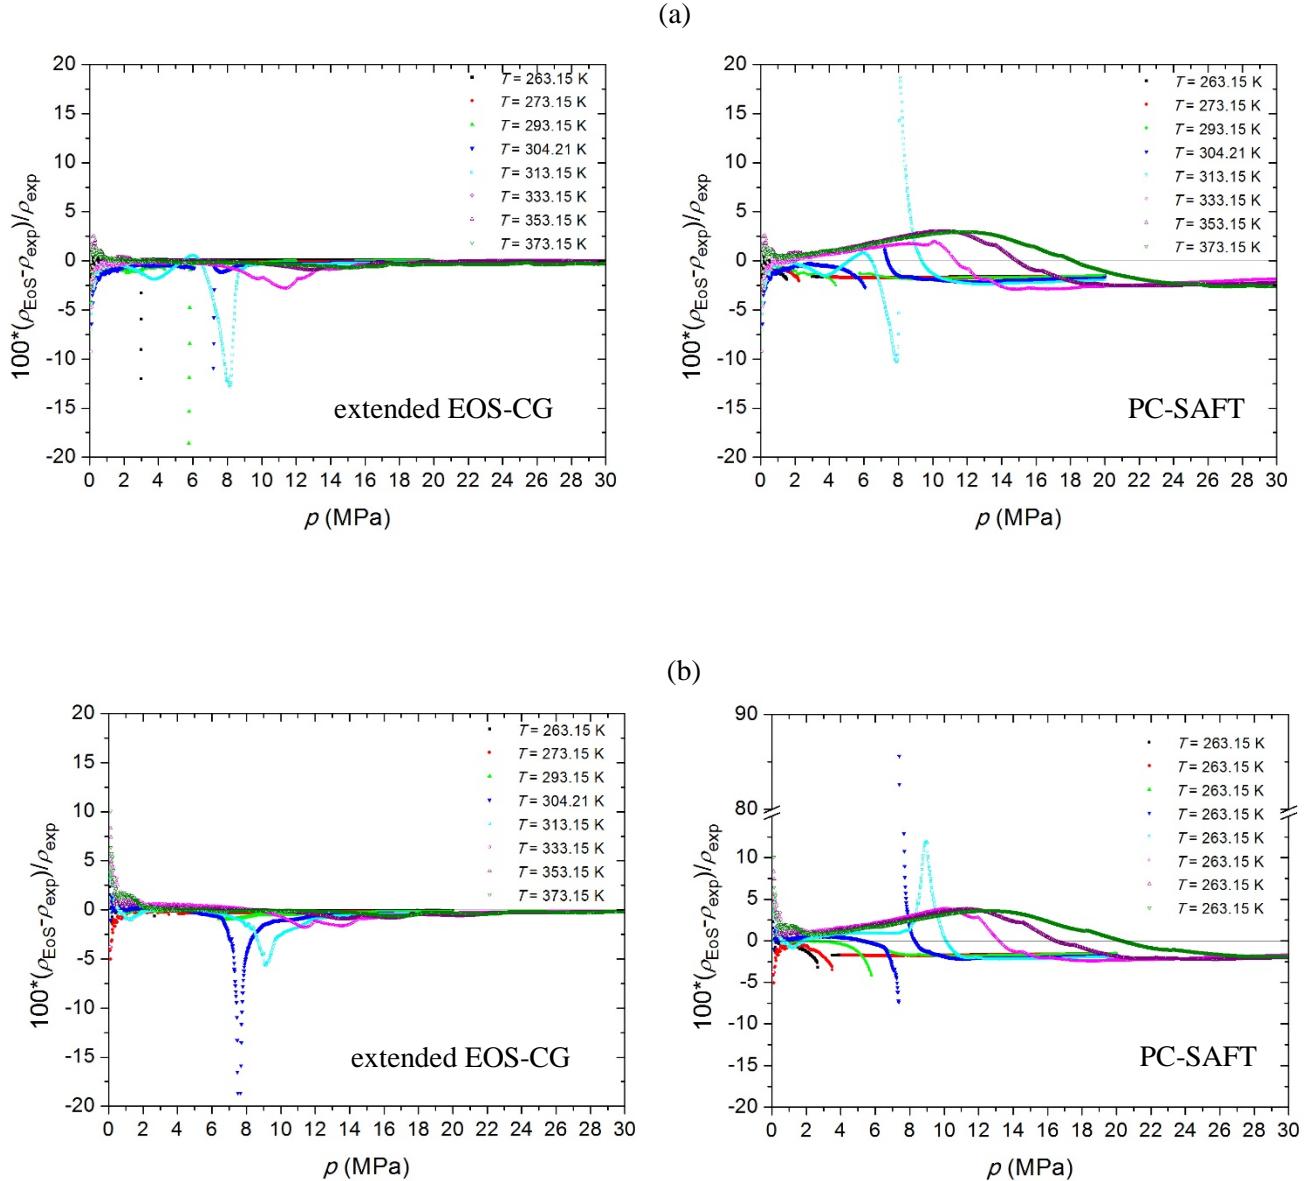

Figure S5. Relative deviations between the experimental speed of sound, c_{exp} , in this work and the values calculated from the extended EOS-CG and PC-SAFT EoSs, c_{EoS} , for Mixtures 2 (co-capture) (a) and 4 (emissions) (b) at the nominal temperatures, T .

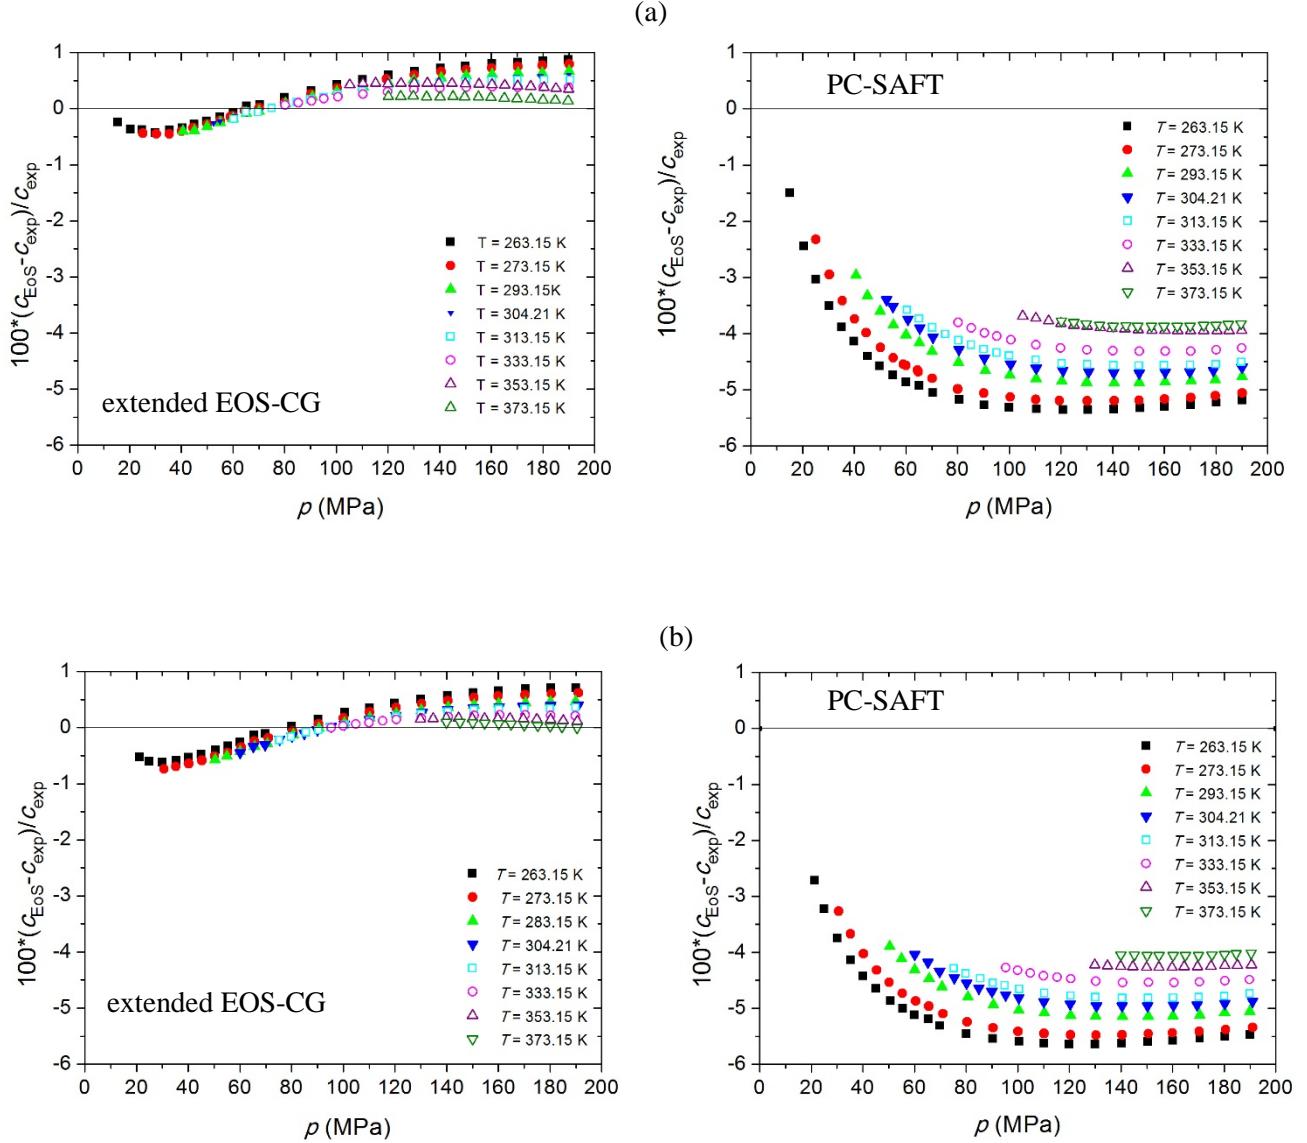

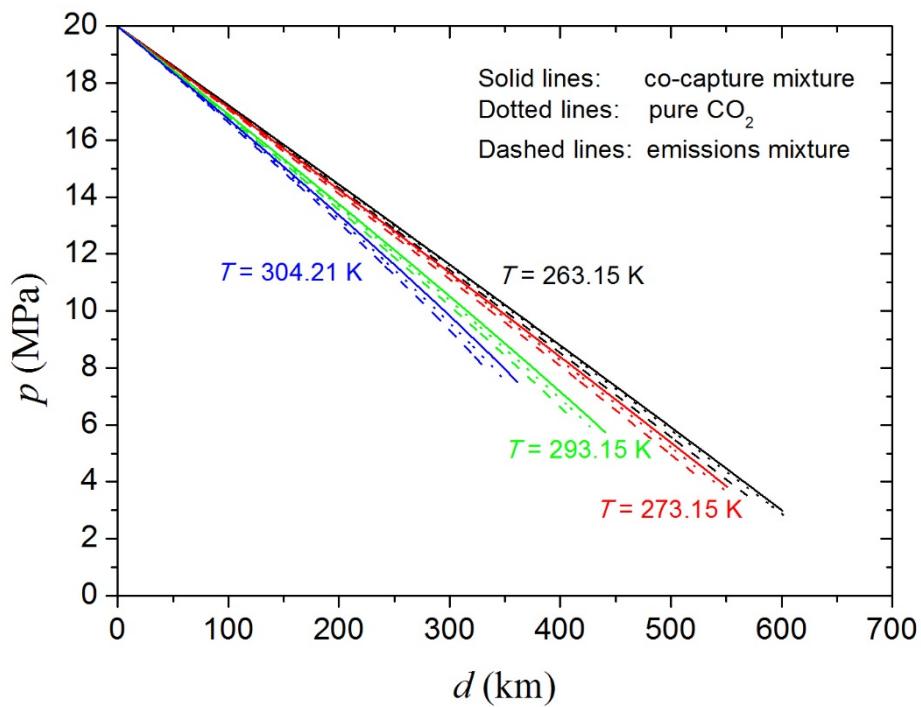

Figure S6. Comparison of pressure (a) and density (b) profiles along the pipeline for Mixtures 1 (co-capture) and 3 (emissions) and for pure CO₂ at several transport temperatures T . A mass flow of $m = 317.1$ kg/s, an inner diameter of the pipeline of $D = 0.508$ m, and a roughness height of $e = 4.6 \times 10^{-5}$ m were used, along with a pipeline inlet pressure of 20.00 MPa.

(a)

(b)

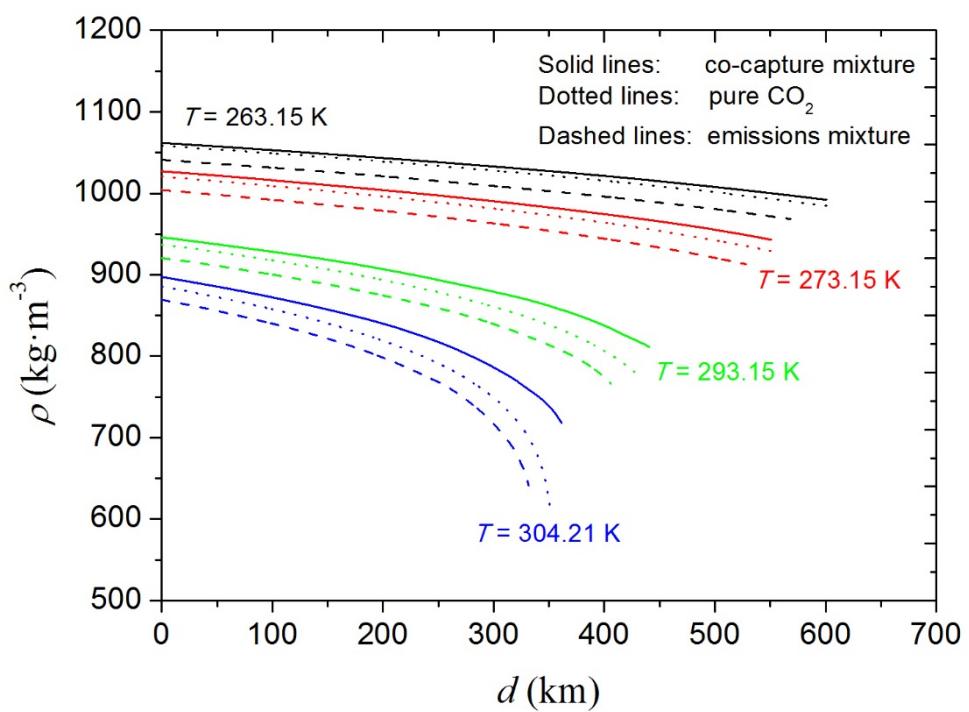

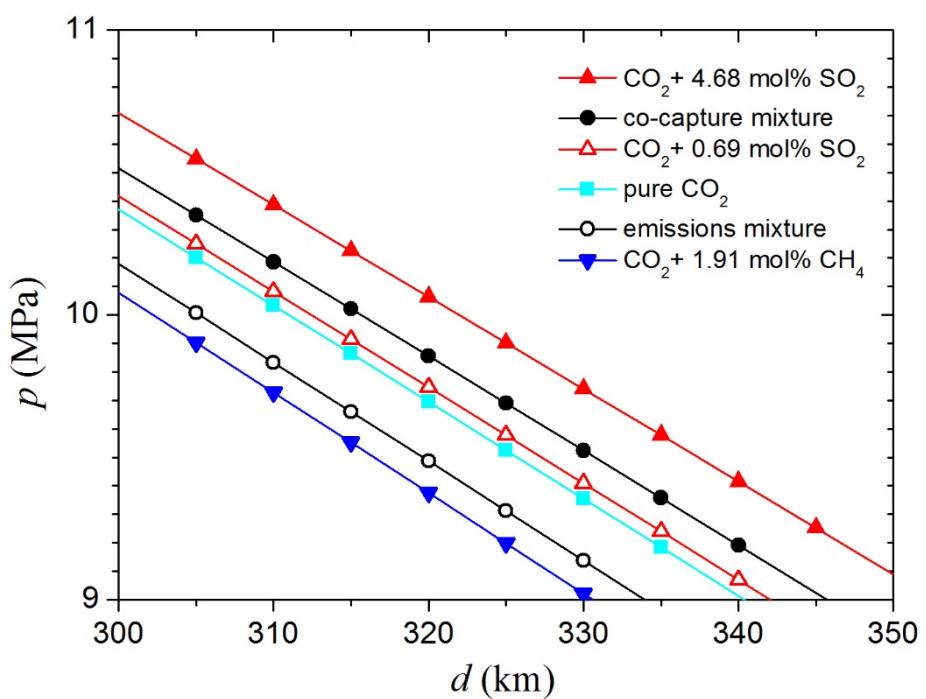

Figure S7. Comparison of pressure (a) and density (b) profiles along the pipeline for the co-capture mixture, the emissions mixture, pure CO₂, CO₂+SO₂ with $x_{\text{SO}_2} = 0.0468$ [8], CO₂+SO₂ with $x_{\text{SO}_2} = 0.0069$ [8], and CO₂+CH₄ with $x_{\text{CH}_4} = 0.0191$ [21] at 293.15 K. A mass flow of $m = 317.1$ kg/s, an inner diameter of the pipeline of $D = 0.508$ m, and a roughness height of $e = 4.6 \times 10^{-5}$ m were used, along with a pipeline inlet pressure of 20.00 MPa.

(a)

(b)

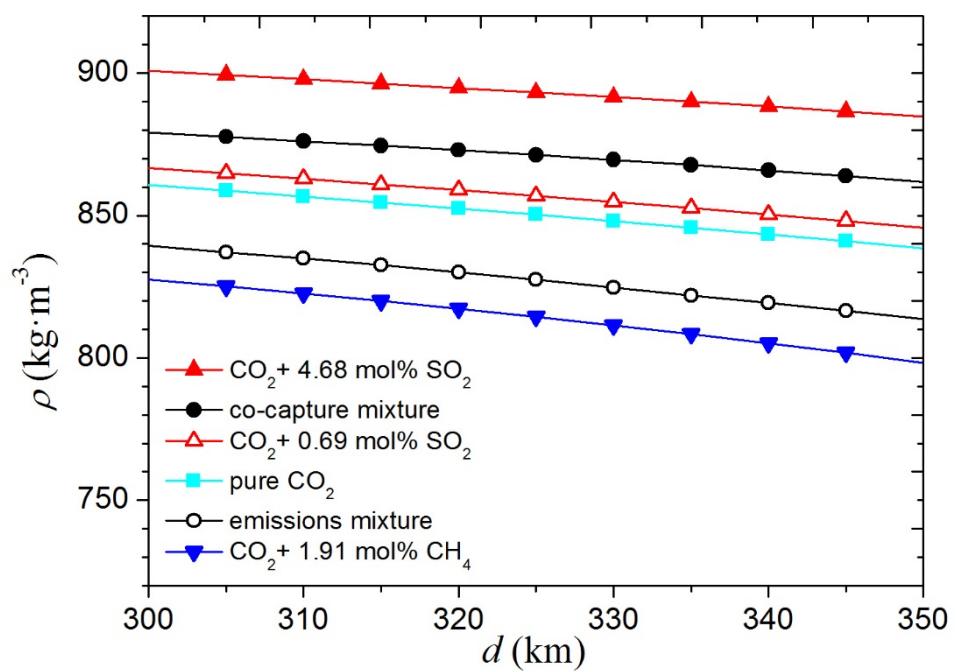

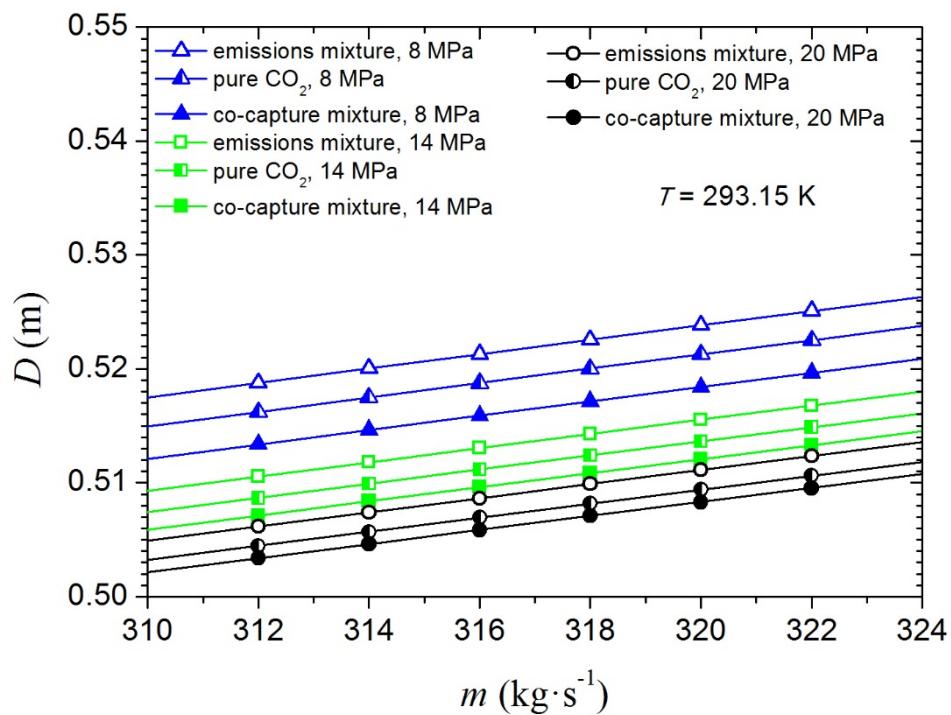

Figure S8. Pipeline inner diameter, D , versus mass flow (capacity), m , for Mixtures 1 (co-capture) and 2 (emissions) and for pure CO₂. (a) at 293.15 K and 8, 14, and 20 MPa; (b) at 14.00 MPa and 263.15, 273.15, 293.15 K, and 304.21 K. The roughness height was set at $e = 4.6 \times 10^{-5}$ m, and an average value for pressure drop per meter of 31.1 Pa·m⁻¹ was used.

(a)

(b)

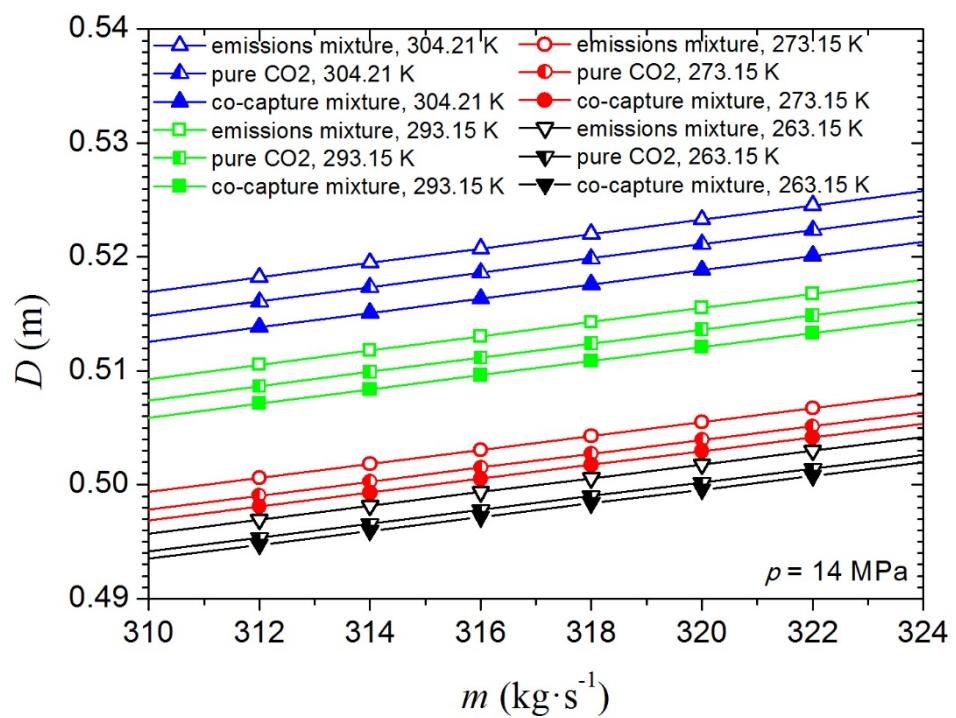

Figure S9. Pipeline inner diameter, D , versus mass flow (capacity), m , for the co-capture mixture, the emissions mixture, pure CO_2 , CO_2+SO_2 with $x_{\text{SO}_2}=0.0468$ [8], CO_2+SO_2 with $x_{\text{SO}_2}=0.0069$ [8], and CO_2+CH_4 with $x_{\text{CH}_4}=0.0191$ [21] at 293.15 K and 14 MPa. The roughness height was set at $e=4.6\times 10^{-5}$ m, and an average value for the pressure drop per meter of 31.1 $\text{Pa}\cdot\text{m}^{-1}$ was used.

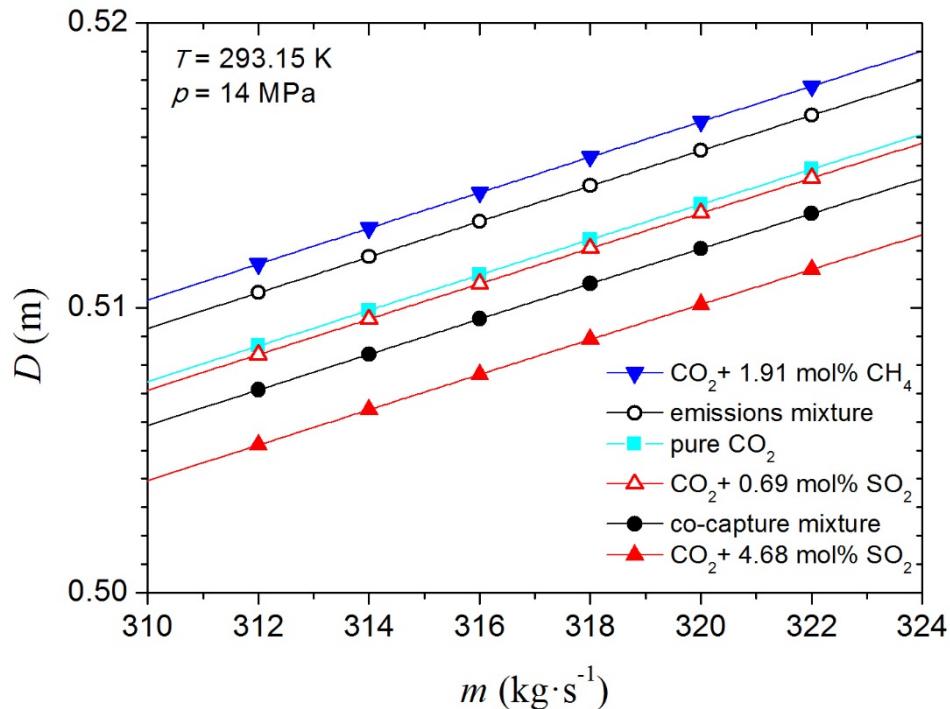

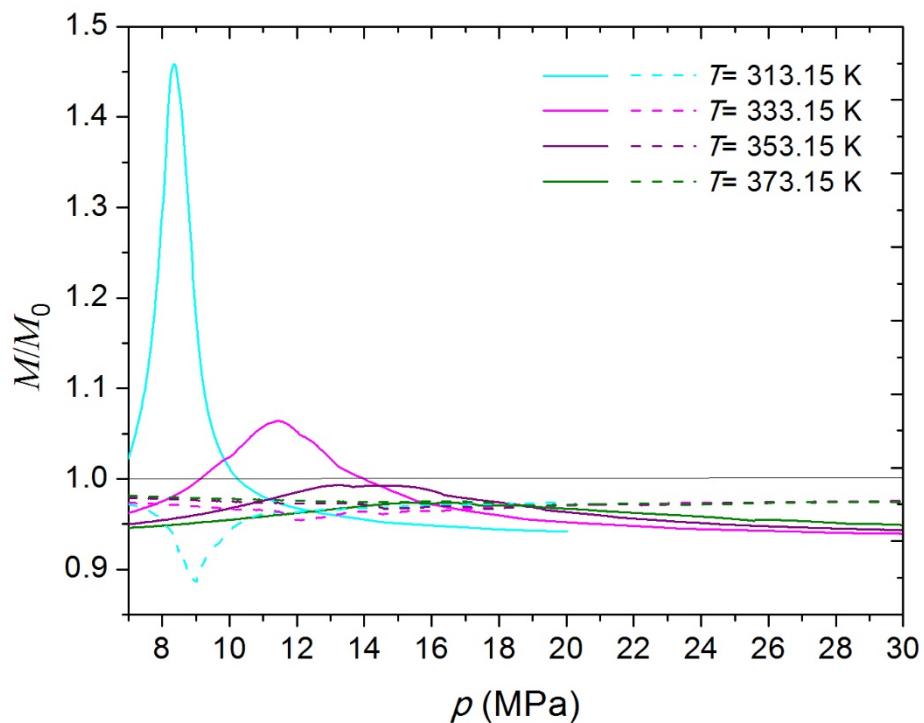

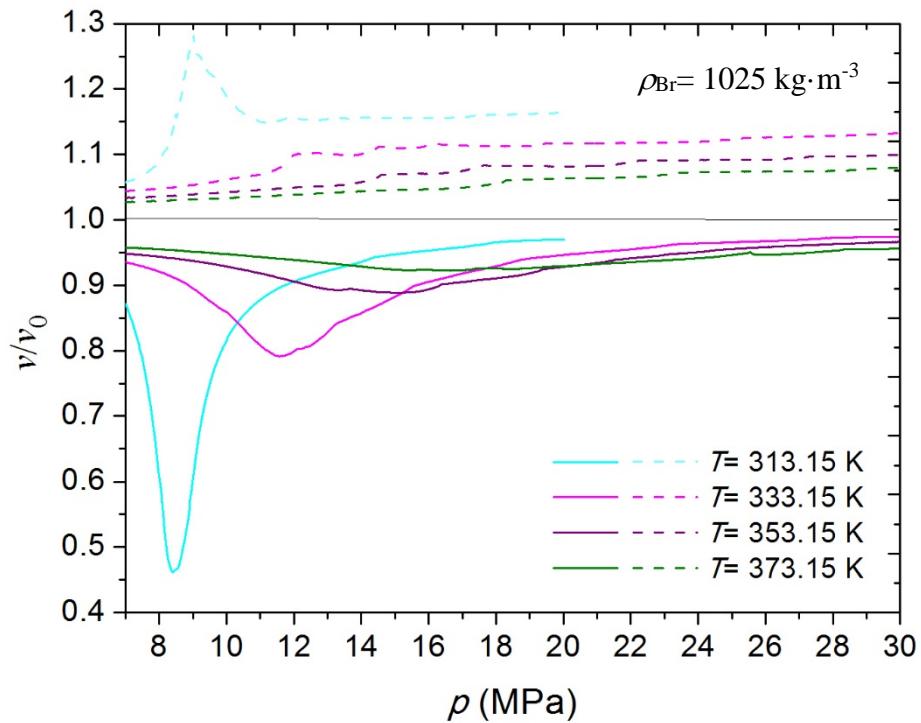

Figure S10. Normalized storage capacity, M/M_0 (a), normalized rising velocity, v/v_0 (b), and normalized permeation flux, \dot{M}/\dot{M}_0 (c), for Mixtures 1, co-capture, (solid line) and 3, emissions, (dashed line) versus pressure, p , at the nominal temperatures, T .

(a)

(b)

(c)

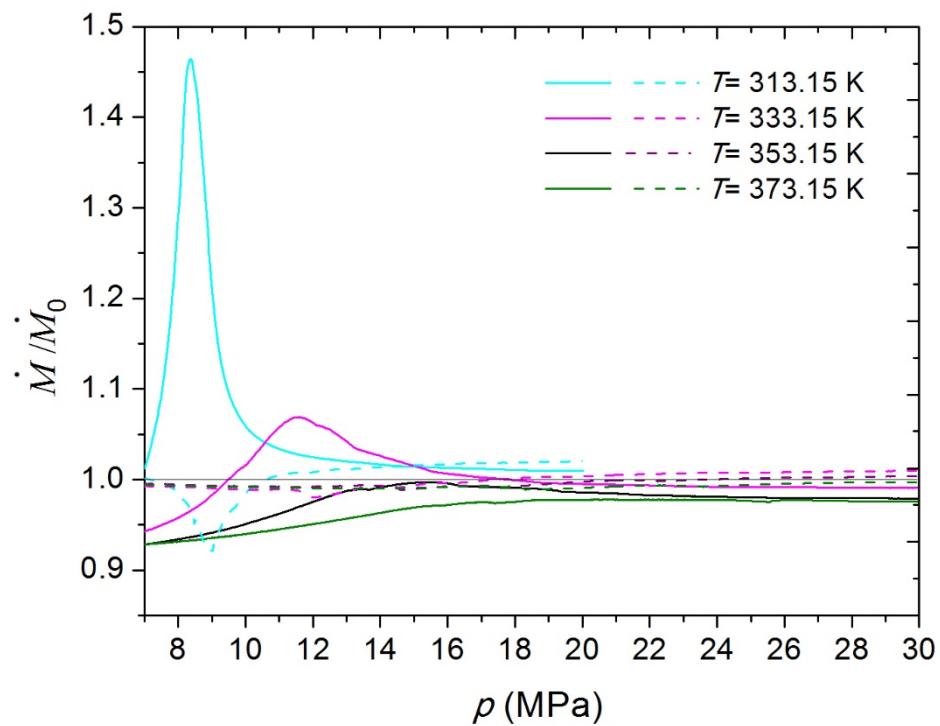

Figure S11. Normalized permeation flux, \dot{M}/\dot{M}_0 , for the co-capture mixture, the emissions mixture, CO_2+SO_2 with $x_{\text{SO}_2}=0.0468$ [8], CO_2+SO_2 with $x_{\text{SO}_2}=0.0069$ [8], and CO_2+CH_4 with $x_{\text{CH}_4}=0.0191$ [21] at the reservoir conditions presented in Table 1 [22-28].
