Abstract

This paper presents an experimental research work in order to obtain the main hygrothermal properties of different mixes of lightweight concrete (LWC) produced from expanded clay. Nowadays, the current state of art assumes an exponential relationship between the moisture content and the thermal properties for this kind of building material. The prime novelty of this study is the experimental determination of the actual hygrothermal properties for different LWC mixes with material densities ranging from 900 to 1400 kg/m³, as well as the least squares best-fitting curves in order to obtain accurate mathematical expressions that permit us to optimize the hygrothermal behaviour of new construction products made up of LWC. In this way, the experimental data set is compared with those for the Standard and a new analytical solution is obtained, giving place to a new analytical solution taking into account the relationship among the heat, moisture and density. Finally, the results and conclusions reached in this work are exposed.

5 **1. Introduction**
6
7
8
9
10
11
12
13
14
15
16

17 In recent years, many researchers have studied the thermal and mechanical properties of
18 different materials used in buildings, such as normal weight concrete (NWC),
19 **lightweight concrete (LWC), gypsum, plaster and clay brick [1-8].**

43 LWC has been used in many constructions due to its significant benefits from the
44 structural and thermal points of view. However, more research is necessary to
45 understand the hygrothermal behavior of this porous material. In order to investigate its
46 hygrothermal performance, it is necessary to take into account the material density and
47 its moisture sorption capacity. LWC density typically ranges from 1000 to 1800 kg/m³
48 compared with that of 2400 kg/m³ for NWC. The main advantages of the LWC are the
49 reduction in the dead weight of the structure and good thermal insulation properties due
50 to the cellular structure of the aggregates. The main disadvantage is the porous structure
51 of the aggregate that implies absorption of a significant quantity of the mixing water.
52 This fact has influence in the thermal [7, 8] and mechanical [4] properties of the LWC,
53 causing energy losses and failure cracks, respectively.
54
55
56

57 Nowadays, the LWC porous material is an important research subject in both heat and
58 moisture transfer points of view due to its attractive characteristics, such as its thermal
59 and acoustic good physical properties, even at high temperatures [8-10]. Some benefits
60 of this research have been applied to the study of the energy efficiency of buildings
61 made up of lightweight concrete products [7, 11]. Furthermore, the basics of the
62
63
64
65

1 moisture and heat transfer in porous materials are interesting and current fields of
2 research [12-15] due to their important effects on those steps to avoid the climate
3 change. However, it is possible to state that many recent research studies have often
4 been focused on analytical or numerical investigations instead of experimental
5 measurements [13, 15].

15
16

17 The fundamental references for this research work are those in building physics and
18 focusing on porous building materials and their properties with respect to the heat and
19 moisture transfer. The interested reader is encouraged to consult several recent research
20 works in this field such as advances in simulation tools [10, 11, 13], property
21 measurements [9, 14] and analytical and numerical models [16, 17]. To motivate this
22 discussion, there is a huge interest in the comprehensive study of the heat and moisture
23 transfer between indoor air and hygroscopic building materials due to changes in the
24 indoor humidity since it is clear that this phenomenon may improve air quality and
25 comfort in buildings [18]. In other words, it is necessary to obtain new experimental
26 data to accurately quantify the heat and moisture transfer between hygroscopic building
27 materials and air if the humidity conditions are varied in a cyclical form. Furthermore,
28 these experimental data are also important and a prerequisite for the numerical models
29 that will be used in developing new building products based on LWC.

2. Materials and methods

2.1. Material properties

The materials used in this research include expanded clay as the main **lightweight aggregate (LWA)**, lightweight sand (LWS) (see Fig. 1), cement and silica sand. The particle size of the expanded clay ranges from 4 to 12.5 mm for LWA and from 1 to 5 mm for LWS, respectively.

Expanded clay is an artificial **lightweight aggregate** that is produced firing natural clay in a rotary kiln at the temperature about 1100°C using a process called “pyroprocessing”, which causes the material to expand. The high proportion of semi-closed pores in LWA creates a cellular pore system that supplies to these **aggregates** their low-particle relative density and good thermal insulated properties.

Fig. 1. Expanded clay aggregates used in this research: LWA (left) and LWS (right).

Table 1

Mix proportions of the LWC samples.

1
2 A total of six samples of 0.2 meters width, 0.2 meters long and 0.05 meters thick for
3 different mix proportions (see Table 1) are tested. **First of all, the specimens are built in**
4 **an isolated wood cast in which they are cured during forty eight hours in the laboratory**
5 **at 23°C and 48% relative humidity.** Next, they were moved from the mould to an oven
6 at 110°C for 24 hours to achieve the entire dryness of the samples. Then, a 1 mm thick
7 gypsum plaster on both sides is applied, and these specimens are again dried inside the
8 oven for 24 hours more. Finally, it was dried other 72 hours to get an environmental
9 steady state with the laboratory conditions (23°C and 48% relative humidity). Table 2
10 shows the densities of the LWC samples tested in this research work.

2.2. Experimental facility

37 The experimental determination of the LWC hygrothermal properties is carried out
38 using a special testing device based on the Standard's test method for the thermal
39 performance of building assemblies using a *hot-box* apparatus [20, 21]. The special
40 testing device is composed of a climatic chamber connected to an isolated hot-box unit
41 (see Figs. 2 and 3). The thermally isolated hot-box has one cubic meter in volume.

9

2.3. Hygroscopic test methodology

10 The Standard ISO 12571:2000 has been used in this research [22]. This Standard is used
11 in this work in order to develop a new test methodology to determine the hygroscopic
12 sorption isotherm of the LWC construction material.
13
14
15
16
17
18
19

20 A variant of the air-conditioned room method indicated in the Standard [22] for a
21 climatic test chamber is used in this experimental setup (see Fig. 4). This layout allows
22 that the temperature inside the test chamber remains constant ($23 \pm 0.5^\circ\text{C}$) as well as an
23 increase of the relative humidity ranging from 21% to 95%.
24
25
26
27
28
29
30
31

32 The moisture content of samples is determined by weighing until to obtain a constant
33 mass so that the equilibrium state is reached in each test. The constant mass is achieved
34 when the mass variation between three consecutive weightings, carried out with a time
35 separation of at least 24 hours, becomes less than 0.1% of the total mass of the sample.
36
37
38
39
40
41
42
43
44

45 The hygroscopic moisture storage is described using the sorption isotherm curves of the
46 material, termed *hygroscopic curves*. These curves establish the relationship between
47 the moisture content for porous media in volume, V , or per unit mass, and the relative
48 humidity of air in equilibrium at constant temperature, ϕ , as follows [22]:
49
50
51
52
53
54
55
56
57
58
59
60
61

$$w(\phi) = \frac{m(\phi) - m_0}{V} \text{ or } u(\phi) = \frac{m(\phi) - m_0}{m_0} = \frac{w(\phi)}{\rho} \quad (1)$$

Fig. 4. Experimental setup (left) and specimens located inside the hot-box test chamber (right) for hygroscopic tests.

2.4. Hygrothermal test methodology

The specific thermal properties determined as a function of the moisture content inside the LWC specimens are: the heat transmission coefficient or *thermal transmittance*, the thermal resistance and the thermal conductivity.

In this way, four samples are placed on a thermal isolated frame using low thermal conductivity foam, located between the test lab environment and the hot-box chamber (see Fig. 5). The hot-box chamber controls the relative humidity and the temperature by means of the climatic generator set so that a dominant horizontal heat flow is achieved.

The temperature, relative humidity and heat flow of the specimen sides are measured to determine the thermal properties of the samples in each test at steady state conditions. For each specimen, five hygrothermal SHT75 capacitive sensors and one HFP01 heat flux sensor are used (see Fig. 5(a-c)). Three hygrothermal sensors are placed on the inner side of the sample (see Fig. 5(d)), and the other two sensors on the external side (see Fig. 5(e)). These sensors are protected with filter caps type SF1 (see Fig. 5(a)) in order to measure the relative humidity and the temperature on the surfaces of the

specimens by means of a data acquisition system (see Fig. 6). Heat flux sensors are placed on the cold side of the samples at room environment (see Fig. 5(e)). Specifically, the hygrothermal conductivity test has taken about 18 hours to complete: 234 hours in total.

Fig. 5. Hygrothermal test setup: (a) a filter cap type SF1, (b) a hygrothermal sensor type SHT75, (c) a thermal flux sensor type HP01, (d) specimens with three sensors type SF1 located on the inner side, (e) specimens with two hygrothermal and one thermal flux sensors on the external side.

Fig. 6. Data acquisition system from temperature and humidity sensors type SHT75.

The main hygrothermal properties are obtained taking into account the following expressions [7, 22, 23]:

$$U = \frac{q}{\Delta T} \quad (2)$$

$$R = \frac{1}{U} + R_{se} + R_{si} \quad (3)$$

$$\lambda = \frac{L}{R} \quad (4)$$

where the value used for the surface thermal resistance of the specimen inside and outside the hot-box test chamber as a function of wind velocity is $0.04 \text{ m}^2 \text{K/W}$.

2.5. Tests conditions

The test conditions of the experimental tests are:

- Number of samples: six.
- Test environment conditions tested: eleven.
- Volume of each sample: 0.003 m^3 .
- Precision weighing balance's accuracy (for hygroscopic tests): $\pm 0.1 \text{ g}$, 10 kg is the maximum weight allowed.
- **Laboratory conditions:** $23 \pm 1 \text{ }^\circ\text{C}$ of temperature and $48 \pm 2.5 \%$ of relative humidity.
- Experimental setup: climatic chamber described in subsection 2.3, based on the standards [20-22] using the hot-box apparatus.
- Test site: Moisture Laboratory at High Polytechnic Engineering College of Gijón (University of Oviedo, Principality of Asturias, Northern Spain).

3. Experimental results

The experimental results for the different mixes of LWC studied in this research work are follows as:

- Hygroscopic sorption isotherm (see Eq. 1), used to describe the equilibrium moisture content of the material at a specified constant temperature [22].
- Hygrothermal conductivity or thermal conductivity for different moisture contents (see Eqs. 2, 3 and 4).

1
2
3
4
5 *3.1. Hygroscopic sorption tests and results*

6
7 The experimental setup described previously is able to test the hygroscopic properties of
8 several specimens at the same time (see Fig. 4).
9
10

11
12
13
14 The sorption isotherms of the samples checked, the relative humidity as a function of
15 the moisture content expressed in kg/m³, are shown in Figs. 7, 8 and 9. Table 3 shows
16
17
18 the moisture content per unit mass (kg/kg) for the relative humidity points tested.

1 • The testing methodology developed in this research work, based on the Standard
 2 ISO 12571:2000 [22], is useful to determine the hygroscopic sorption curve of
 3 different samples.
 4
 5 • The sorption isotherms of the samples obtained in the tests (see Figs. 7, 8 and 9)
 6 and the moisture content per unit mass (see Table 3) show clearly that the
 7 moisture absorption is increased in the samples if their density is decreased.

20 3.2. *Hygrothermal conductivity tests*

21
 22 The experimental measurement of the LWC hygrothermal properties is performed by
 23 means of the same experimental device (see Fig. 5d-e). Specifically, four specimens are
 24
 25 located on a thermal isolated frame at the open front side of the hot-box apparatus.

26
 27
 28 The temperature differences between the internal and external sides of the specimens
 29 located at the hot-box are greater than 15°C in all the tests. This value is recommended
 30 by the Standards [20, 21] for these thermal tests. The results obtained for the samples
 31
 32 checked are shown in Fig. 10. Additionally, Table 4 shows only the experimental LWC
 33 thermal properties for a specific relative humidity equal to 50%.

59
60
61
62
63
64
65

Taking into account the results of the tests carried out, the following findings for the hygrothermal properties test of the LWC mixes are:

- The hot-box test chamber provides a stable test environment in order to determine the thermal properties of building elements.
- The laboratory values of the thermal properties belong to the usual range for this LWC material, achieving similar results on specimens of the same type (see Table 4).
- **Fig. 11 shows a set of nine thermal imaging photographs corresponding to three samples tested (1A, 2A and 3A) with different moisture contents (10%, 50% and 80%). In all the rows and from left to right, the outside temperature is increased if the moisture content of the sample is also increased. Similarly, in all the**

1
2 columns and from upper to lower, the outside temperature grows if the sample
3 density is increased.

7
8
9

10 **4. Analytical solution and fitted curves**
11
12
13
14
15
16
17
18

In order to obtain the most suitable analytical expressions between the thermal properties, moisture content and density of LWC material, it is necessary to calculate the fitted curves from the previous experimental results.
19
20
21
22

In this sense, the goodness of the fitted curves compared to the observed values is performed using the coefficient of determination as a significant statistic [24, 25]:
23
24
25
26
27

$$r^2 = \frac{\sum_{i=1}^n (Y_i - \hat{Y}_i)^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} \quad (5)$$

In science and engineering it is often the case that an experiment produces a set of data points $(x_1, y_1), \dots, (x_n, y_n)$, where the abscissas $\{x_k\}_{k=1}^n$ are distinct. One goal of numerical methods is to determine a formula $y = f(x)$ that relates these variables. There are several different possibilities for the type of function that can be used. Usually, a class of allowable formulas is chosen and then the coefficients must be determined. Often there are underlying mathematical models, based on the physical process that will determine the form of the function [25, 26]. This is our case in this research work.

25 Next, the fitted curves of several theoretical models have been carried out according to
26
27 the following steps:

- 30 1. Transformations for data linearization of the functions for several nonlinear
31 theoretical models. Once the curve has been chosen, a suitable transformation of
32 the variables must be found so that a linear relation is obtained.
- 33 2. Finding the best fitted curve with least squares fitting technique using the
34 MATLAB software [26].
- 35 3. Refinement of the previous best-fit parameters using a quasi-Newton method. A
36 significant weakness of Newton's method for solving systems of nonlinear
37 equations is that, for each iteration, a Jacobian matrix must be computed and a
38 $n \times n$ linear system solved that involved this matrix. In this work, a
39 generalization of the Secant method to systems of nonlinear equations known as
40 Broyden's method [25] is considered. This method replaces the Jacobian matrix
41 in Newton's method with an approximate matrix for each iteration.

65

In order to obtain the hygroscopic fitted curves, the three most well-known theoretical models to represent the sorption isotherms curves are used:

- The Kunzel model [27, 28]: This model is used by the WUFI moisture transport simulation software, developed at the Fraunhofer-Institut für Bauphysik of Stuttgart. Its mathematical expression is:

$$w(\phi) = w_{\lim} \frac{(b-1) \cdot \phi}{b - \phi} \quad (6)$$

where w_{\lim} and b are the coefficients of the fitted curve.

- The Kumaran model: The catalogue of material properties published in the Annex 14 of the International Energy Agency (IEA) [29, 30], proposes the following function:

$$w(\phi; a, b, c) = \frac{\phi}{a\phi^2 + b\phi + c} \quad (7)$$

where a , b and c are the coefficients of the fitted curve.

- The Burch model: It was developed by the United States Department of Energy for the MOIST simulation program [31, 32] as follows:

$$w(\phi; A, B) = A \left[\frac{1}{1-\phi} - 1 \right]^B \quad (8)$$

where A and B are the coefficients of the fitted curve.

In order to fit the experimental data of hygroscopic sorption tests, the functions of the above mentioned theoretical models are used. The values of the coefficients obtained in each of the fitted curves are shown in Table 5.

Table 5

Coefficients of the fitted curves for the hygroscopic tests.

Fig. 12. Hygroscopic fitted curves for the LWC type 1.

Fig. 13. Hygroscopic fitted curves for the LWC type 2.

Fig. 14. Hygroscopic fitted curves for the LWC type 3.

Next, the goodness of fit in each of the curves can be observed in Fig. 15:

Fig. 15. The goodness of fit as a function of the coefficient of determination (r^2) for the hygroscopic tests.

From the previous results, it is obtained the following findings:

- The coefficient of determination indicates that the fitted curves to the theoretical models developed for the IEA (Kumaran model) and the MOIST program [31, 32] (Burch model) are the most appropriate to reproduce the hygroscopic

1 behavior of the tested LWCs. Specifically, the fitted function developed by
2 Burch is a bit better than the Kumaran model.

65

- The function developed by Kunzel for the WUFI program [27, 28] is the worst-fitting curve and it does not fulfill the requirements of the minimum required goodness.

18 Therefore, in the hygrothermal fitted curves we will use the Burch model to obtain the
19 moisture content per unit mass as a function of relative humidity for each type of LWC
20
21 tested.

27 4.2. *Hygrothermal fitted curves and response surface*

28 The conversion of thermal values from a set of conditions (λ_1) to another set of
29 conditions (λ_2) is carried out in accordance with the following expression [19]:
30
31
32
33
34
35
36
37

61
62
63
64
65

$$\lambda_2 = \lambda_1 \cdot F_T \cdot F_m \cdot F_a \quad (9)$$

40 In this case, it is assumed that there is no influence of the aging ($F_a = 1$) and the
41 temperature variation ($F_T = 1$). The standard rule UNE-EN ISO 10456 [19] establishes a
42 conversion factor, F_{m_i} , for the moisture content as a function of the moisture content per
43 unit mass for the i -th set of conditions, u_i , through the conversion coefficient, f_u . In this
44 investigation, we have determined u as a function of the relative humidity using the
45 Burch model as it is indicated in the previous subsection 4.1, giving place to the
46 following equation for the conversion factor [19]:
47

61
62
63
64
65

$$F_{m_i}(\phi) = e^{f_u(u_i(\phi) - u_{50\%})} \quad (10)$$

Until now, Table A.20 in Annex A of the standard rule UNE-EN ISO 10456 [19] takes a conversion coefficient $f_u = 4$ with a moisture content per unit mass ranging from 0 to 0.25 kg/kg, in case of that the expanded clay is used as main aggregate.

Next, Figs. 16, 17 and 18 show the fitted curves corresponding to the thermal conductivity as a function of the relative humidity for the following cases:

1. Value recommended by the standard rule [19] ($f_u = 4$):

$$\lambda(\phi) = \lambda_{50\%} \cdot e^{f_u(u_i(\phi) - u_{50\%})} \quad (11)$$

2. Value of conversion coefficient different from the standard rule ($f_u = 16$):

$$\lambda(\phi) = \lambda_{50\%} \cdot e^{f_u(u_i(\phi) - u_{50\%})} \quad (12)$$

3. A cubic function :

$$\lambda(\phi) = a \cdot \phi^3 + b \cdot \phi^2 + c \cdot \phi + d \quad (13)$$

where a , b and c are the coefficients of the fitted curve.

4. A logistic function for the conversion coefficient $f_u = 4$ (Logistic plus Standard):

$$\lambda(\phi) = A \cdot \lambda_{50\%} \cdot \frac{1 + m \cdot e^{-\frac{\phi}{B}}}{1 + n \cdot e^{-\frac{\phi}{B}}} \quad (14)$$

1
2 where A and B are the coefficients of the fitted curve.

40 In this sense, Fig. 19 shows the goodness of fit as a function of the coefficient of
41 determination, r^2 , for all the LWC mixes from the laboratory tests. Specifically, the
42 coefficient of determination for the recommended value of the standard rule ranges from
43 0.28 to 0.33; for the modified value $f_u = 16$, it ranges from 0.66 to 0.83; for the cubic
44 function, it ranges from 0.95 to 0.97; and finally, it ranges from 0.95 to 0.96 for the
45 logistic function.

$$\lambda(\rho, \phi) = s(\rho) \cdot \lambda_{50\%}(\rho) \cdot F_m(\rho, \phi) \cdot \frac{1 + m(\rho) \cdot e^{-\phi/r(\rho)}}{1 + n(\rho) \cdot e^{-\phi/r(\rho)}} \quad (15)$$

As might be observed in Fig. 20, the thermal conductivity surface grows if the relative humidity and the material density are increased according to the previous results [7, 11].

Fig. 20. Response surface for specimens made up of the expanded clay (main aggregate) corresponding to the fitted curve according to the Standard ($f_u = 4$) [19], amended by a logistic function.

Table 6 shows the specific values of the LWC thermal conductivity as a function of the most representative values of the density with respect to the relative humidity within the range studied.

Table 6

Values of the LWC thermal conductivity as a function of the most representative values of the density with respect to the relative humidity.

5. Conclusions

Based on the experimental results and numerical fitting study of this investigation, the following findings can be drawn:

1. A new experimental procedure for the calculation of the hygroscopic sorption isotherm curves based on the standard UNE-EN ISO 12571:2000 [22] was

1
2 developed, and it was applied to the study of the hygroscopic properties of three
3 different LWC mixes with success.
4
5
6

7 2. We have compared the experimental results with the theoretical models
8 developed by Kumaran, Burch and Kunzel [27-32] and we have calculated the
9 best fitting parameters in each one of them. As a consequence, it is shown that
10 the Burch model is the most suitable to reproduce the actual hygroscopic
11 behavior of the LWCs tested.
12
13 3. A new testing methodology was built to obtain the hygrothermal properties
14 based on the standards UNE-EN ISO 8990 and ASTM C 1363 [20, 21], and it
15 was applied to the study of the hygrothermal behaviour of three different LWC
16 mixes.
17
18 4. From the hygrothermal tests, the best-fitting curves based on analytical functions
19 and the standard rule UNE-EN ISO 10456 [19] have been obtained. It is possible
20 to state that the values of the conversion coefficients used in the standard rule in
21 case of expanded clay as the main aggregate of the LWC material must be
22 updated according to our laboratory tests.
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44

45 Finally, this research work proposes for all the LWC mixes, with densities between 900
46 and 1400 kg/m³ and moisture content ranging from 0 to 0.25 kg/kg, a change of the
47 standard rule's conversion coefficients from 4 to 16 (see Table A.20. of the standard
48 [19]). Other two feasible possibilities are:
49
50
51
52
53
54

- 55 • A logistic function with a conversion coefficient $f_u = 4$. This fitted curve shows
56 a hygrothermal behavior in agreement with the laboratory tests.
57
58

- A cubic function also presents a good fit from the hygrothermal point of view according to the laboratory tests.

2A	0.78	0.72	0.675	0.54	0.36
2B	0.78	0.72	0.675	0.54	0.36
3A	0.84	0	2.4	0.54	0.39
3B	0.84	0	2.4	0.54	0.39

^(*)Note: LWA: 4-12.5 mm particle diameter, and LWS: 1-5 mm particle diameter.

Table 2

Densities of the LWC determined in this investigation during the manufacturing process.

Sample	Fresh density (kg/m³)	Oven dry density (kg/m³)	Equilibrium density (kg/m³)
1A	1027	953	973
1B	992	948	971
2A	1055	979	999
2B	1058	1,001	1,026
3A	1460	1,353	1,373
3B	1460	1,338	1,362

Table 3

Experimental results of the LWC moisture content per unit mass (kg/kg) for the relative humidity (%) points tested.

LWC type	$\phi(\%)$									
	10	15	22	35	50	65	75	80	85	95
1	0.0111	0.0134	0.0150	0.0165	0.0179	0.0194	0.0209	0.0225	0.0238	0.0251
2	0.0102	0.0127	0.0147	0.0161	0.0176	0.0195	0.0209	0.0224	0.0237	0.0250
3	0.0069	0.0086	0.0099	0.0110	0.0119	0.0131	0.0138	0.0148	0.0158	0.0166

Table 4

Experimental results of the LWC thermal properties for a relative humidity equal to 50%.

Sample	Density (Kg/m ³)	q (W/m ²)	ΔT (K)	U (W/m ² K)	R (m ² K/W)	λ (W/mK)	ϕ (%)
1A	973	96.357	19.647	4.904	0.284	0.176	50
1B	971	95.839	20.058	4.778	0.289	0.173	50
2A	999	93.319	17.598	5.303	0.269	0.186	50
2B	1,026	94.533	17.549	5.387	0.266	0.188	50
3A	1,373	115.260	13.075	8.815	0.193	0.258	50
3B	1,362	114.068	13.142	8.680	0.195	0.256	50

Table 5

Coefficients of the fitted curves for the hygroscopic tests.

	Kunzel model (WUFI)		Kumaran model (IEA)		Burch model (MOIST)
LWC type 1					
w_{\lim}	23.9438	a	-0.04039605	A	17.6040545
