Abstract

In this paper we consider a 1D parabolic singularly perturbed reaction-convection-diffusion problem, which has a small parameter in both the diffusion term (multiplied by the parameter $\varepsilon^2$) and the convection term (multiplied by the parameter $\mu$) in the differential equation ($\varepsilon \in (0, 1]$, $\mu \in [0, 1]$, $\mu \leq \varepsilon$). Moreover, the convective term degenerates inside the spatial domain, and also the source term has a discontinuity of first kind on the degeneration line. In general, for sufficiently small values of the diffusion and the convection parameters, the exact solution exhibits an interior layer in a neighborhood of the interior degeneration point and also a boundary layer in a neighborhood of both end points of the spatial domain. We study the asymptotic behavior of the exact solution with respect to both parameters and we construct a monotone finite difference scheme, which combines the implicit Euler method, defined on a uniform mesh, to discretize in time, together with the classical upwind finite difference scheme, defined on an appropriate nonuniform mesh of Shishkin type, to discretize in space. The numerical scheme converges in the maximum norm uniformly in $\varepsilon$ and $\mu$, having first order in time and almost first order in space. Illustrative numerical results corroborating in practice the theoretical results are showed.

Key words: 1D parabolic singularly perturbed problems, two parameters, discontinuous source, interior and boundary layers, uniform convergence.

1 Introduction

We consider the singularly perturbed initial-boundary value problem

\[ Lu(x,t) = f(x,t), \quad (x,t) \in G \setminus S^\pm, \]
\[ u(x,t) = \varphi(x,t), \quad (x,t) \in S, \]
\[ l^\pm u(x,t) \equiv \varepsilon \left[ \frac{\partial}{\partial x} u(x+0,t) - \frac{\partial}{\partial x} u(x-0,t) \right] = 0, \quad (x,t) \in S^\pm, \]

where the differential operator \( L \) is given by

\[ L u(x,t) \equiv \left\{ \varepsilon^2 \frac{\partial^2}{\partial x^2} + \mu x^{2p+1} a(x) \frac{\partial}{\partial x} - b(x,t) \frac{\partial}{\partial t} - r(x,t) \right\} u(x,t), \]

with \( G = D \times (0, T], \) \( D = (-d, d), d > 0, S = \overline{G} \setminus G \) and \( S^\pm = \{ x = 0 \} \times (0, T]. \)

We assume that
\[ 0 \leq \mu \leq 1, \quad 0 < \varepsilon \leq 1, \quad \mu \leq \varepsilon, \]

\[ p \] is a nonnegative integer, \( a, b \) and \( r \) are sufficiently smooth functions such that
\[ a(x) > 0, \quad b(x,t) \geq \beta > 0, \quad r(x,t) \geq 2r_0^2, \quad \text{with } r_0 > 0 \text{ for } (x,t) \in \overline{G}, \]

and the source function \( f(x,t) \) is continuous on \( \overline{G}^+ \) and \( \overline{G}^-, \) where \( \overline{G}^- = [-d, 0] \times [0, T], \) \( \overline{G}^+ = [0, d] \times [0, T], \) and it has a first kind discontinuity on the set \( S^\pm. \) Moreover, we assume that the data of problem (1) satisfy sufficient regularity conditions that guarantee the smoothness of the solution on the sets \( \overline{G}^+ \) and \( \overline{G}^- \) required in the analysis below.

We denote by \( S = S^L \cup S_0, S_0 = S^+_0 \cup S^-_0, S^L = S^L \cup S^r, \) where

\[ S_0 = [-d,d] \times \{ t = 0 \}, \quad S^+_0 = [0,d] \times \{ t = 0 \}, \quad S^-_0 = [-d,0] \times \{ t = 0 \}, \]
\[ S^L = \{ x = -d \} \times (0,T], \quad S^r = \{ x = d \} \times (0,T]. \]

The sets described above are displayed in Figure 1.

Moreover, compatibility conditions at the corners \((-d,0),(0,0)\) and \((d,0)\) are satisfied that guarantee the required smoothness of the solution in the neighborhoods of these points. We refer to [1] for a discussion of the required regularity and compatibility conditions in our analysis.

Problems for partial differential equations with discontinuous data are simple models of diffraction problems. In [2,3] the case of regular equations was discussed. The analysis of special methods for singularly perturbed problems
with discontinuous data and degenerating convective terms has been little
developed in the literature. In [4–6] a problem with discontinuous data in
differential equations was analyzed; in [7] a problem with a convective term
degenerating on the domain boundary for a parabolic convection-diffusion
equation was studied. An experimental technique to analyze the $\varepsilon$-uniform
convergence of numerical schemes defined on piecewise-uniform meshes, for a
singularly perturbed elliptic equation when the convective term degenerates
on the boundary, was considered in [8, Chapter 7].

The problem (1), (2) for the simpler case $\mu = 0$ was considered in [9]; in
[1,10,11] a similar problem to (1) for $\mu = 1$ was studied; in those works, it was
proved that the numerical scheme, combining the implicit Euler method on a
uniform mesh in time and the classical upwind scheme on a piecewise uniform
mesh in space, gives a scheme converging $\varepsilon$-uniformly in the maximum norm,
or, in short, uniformly convergent scheme. The analysis is based on a discrete
minimum principle and appropriate estimates of the solution and its partial
derivatives.

In this paper we are interested into extending those results to the more general
case where the small parameters $\varepsilon$ and $\mu$ affect both the convection and the
diffusion coefficients in the differential equation. This class of problems, but
with smooth coefficients and in the absence of turning point, has been analyzed
in [12].

The paper is structured as follows. In Section 2, we analyze the asymptotic
behavior of the exact solution of the continuous problem (1), proving appro-
priate bounds for its derivatives, which will be used in the analysis of the
uniform convergence of the numerical scheme. In Section 3, we construct the
numerical method, combining the implicit Euler to discretize in time and the
upwind finite difference scheme to discretize in space. We prove that, if a uni-
form mesh in time and a special Shishkin type mesh in space are used, then
the scheme is uniformly convergent and it has first order in time and almost
first order in space. Finally, in Section 4, some numerical results are shown,
which corroborate in practice the efficiency of the method and the order of
uniform convergence with respect to both parameters $\varepsilon$, $\mu$, according to the theoretical results.

Henceforth, we denote by $C^{k,k/2}$ the space of functions with continuous derivatives with respect to $x$ up to order $k$ and continuous derivatives with respect to $t$ up to order $k/2$, and by $M$ a generic positive constant independent of the parameters $\varepsilon$, $\mu$ and also of the discretization parameters $N$ and $N_0$, where $N$ and $N_0$ are the number of mesh intervals in the variables $x$ and $t$, respectively.

2 The continuous problem: asymptotic behavior

In this section we study the asymptotic behavior, with respect to $\varepsilon$ and $\mu$, of the exact solution of the continuous problem (1), and we establish appropriate bounds for its partial derivatives. Using a similar technique to this one in [6], the following comparison principle can be proved.

**Lemma 1.** Let assume that the functions $u^1(x,t)$, $u^2(x,t)$ satisfy

$$Lu^1(x, t) \leq Lu^2(x, t), \quad (x, t) \in G \setminus S^\pm,$$

$$t^\pm u^1(x, t) \leq t^\pm u^2(x, t), \quad (x, t) \in S^\pm,$$

$$u^1(x, t) \geq u^2(x, t), \quad (x, t) \in S.$$

Then, it holds that $u^1(x,t) \geq u^2(x,t), \quad (x,t) \in \Gamma$.

We assume that the data of the problem are sufficiently smooth functions and also that they satisfy compatibility conditions in the corner points $(-d, 0)$, $(d, 0)$ and $(0,0)$ in order that the exact solution of (1) belongs to the space $C(\bar{G}) \cap \{C^{4,2}(\bar{G}^-) \cup C^{4,2}(\bar{G}^+)\}$. We use a truncation error argument to prove the uniform convergence of the numerical scheme defined below; thus, we need appropriate bounds of the derivatives of the exact solution which are deduced in this section.

We begin with a lemma where some coarse bounds for the derivatives of $u$ are given.

**Lemma 2.** The solution of the problem (1) satisfies

$$\left| \frac{\partial^{k+k_0}}{\partial x^k \partial t^{k_0}} u(x,t) \right| \leq M \varepsilon^{-k}, \quad (x, t) \in \bar{G}^- \cup \bar{G}^+, \quad 0 \leq k + 2k_0 \leq 4. \quad (4)$$

**Proof.** Using the stretching variables $\xi = \varepsilon^{-1} x$, $\tau = t$, the solution,
\( \hat{u}(\xi, \tau) = \hat{u}(\xi(x), \tau(t)) = u(x, t) \), of the transformed problem satisfies

\[
\left\{ \frac{\partial^2}{\partial \xi^2} + \frac{\mu}{\varepsilon}(\xi \varepsilon)^{2p+1} \frac{\partial}{\partial \xi} - \hat{b}(\xi, \tau) \frac{\partial}{\partial \tau} - \hat{r}(\xi, \tau) \right\} \hat{u}(\xi, \tau) = \hat{f}(\xi, \tau),
\]

\((\xi, \tau) \in \left( -\frac{2}{\varepsilon}, \frac{2}{\varepsilon} \right) \setminus \{0\} \times (0, T]\).

Noting that \( \mu/\varepsilon \leq 1 \), a classical theory (see [13] for full details) brings to the estimate

\[
\left| \frac{\partial^{k+k_0}}{\partial \xi^k \partial \tau^{k_0}} \hat{u}(\xi, \tau) \right| \leq M, \quad 0 \leq k + 2k_0 \leq 4,
\]

and transforming back to the original variables, the bound (4) follows. From estimate (4), it follows that the parameter \( \mu \) in problem (1), (2) is regular.

Nevertheless, these bounds are not sufficient to deduce the uniform convergence of the numerical scheme. Thus, we decompose the exact solution as

\[
u(x, t) = U^+(x, t) + V^+(x, t) + W_R(x, t), \quad (x, t) \in G^+; \]

\[
u(x, t) = U^-(x, t) + V^-(x, t) + W_L(x, t), \quad (x, t) \in G^-.
\]

where \( U^\pm \) is the regular component, \( V^\pm \) is the interior layer component, and \( W_R, W_L \) are the right and left boundary layer components, respectively.

Note that the function \( u(x, t) \), considered on the set \( G^+ \), is the solution of the initial-boundary value problem

\[
Lu(x, t) = f(x, t), \quad (x, t) \in G^+; \]

\[
u(x, t) = \varphi(x, t), \quad (x, t) \in S_0^+ \cup S^r; \]

\[
u(x, t) = \varphi_u(x, t), \quad (x, t) \in S^\pm,
\]

where \( \varphi_u(x, t) = u(x, t), (x, t) \in S^\pm \), and \( u \) is the solution of the problem (1).

From (4), it is straightforward that the derivatives with respect to \( t \) of the function \( \varphi_u(x, t), (x, t) \in S^\pm \) are \( \varepsilon \)-uniformly bounded. Moreover, we assume that the necessary compatibility conditions are fulfilled in the corner points of the set \( G^+ \).

First, to obtain the required bounds for the regular component \( U^+ \), we use the idea of extending the domain problem (see, for example, [1,6]). Let \( G^{+\varepsilon} \) be an extension of the domain \( G^+ \) (for example, one can choose \( G^{+\varepsilon} = [-1, 2] \times [0, 1] \)). The functions \( a, b, r, f \) and \( \varphi \) are smoothly extended to \( G^{+\varepsilon} \) and the
new differential operator is denoted by $L$. We define $U^+(x, t)$ as the restriction to $G^+$ of the function $U^+e(x, t)$, $(x, t) \in G^+$, i.e., $U^+(x, t) = U^+e(x, t)$, $(x, t) \in G^+$, where $U^+e(x, t)$ is the solution of the initial-boundary value problem

\begin{align*}
L^e U^+e(x, t) &= f^+e(x, t), \quad (x, t) \in G^+e, \\
U^+e(x, t) &= \varphi^+e(x, t), \quad (x, t) \in S^+e,
\end{align*}

which is an extension of the problem (6) beyond the sets $S^\pm, S^r$, considered on $G^e$.

The data of the problem (7), the functions $f^+e(x, t)$, $(x, t) \in G^+$ and $\varphi^+e(x, t)$, $(x, t) \in S_0^+ \cup S^r$, on the set $G^+$ are the same data as in (1). In the rest of $G^+e$, they are smooth extensions of the data of (1) prescribed on $G^+$.

In the second place, the function $V^+(x, t)$, $(x, t) \in G^+$, i.e., the singular component of the interior layer, is the solution of the problem

\begin{align*}
LV^+(x, t) &= 0, \quad (x, t) \in G^+, \\
V^+(x, t) &= \varphi V^+(x, t), \quad (x, t) \in S^\pm, \\
V^+(x, t) &= 0, \quad (x, t) \in S_0^+ \cup S^r,
\end{align*}

where $\varphi V^+ = \varphi u(x, t) - U^+(x, t)$, $(x, t) \in S^\pm$.

Third, the left layer component $W_L(x, t)$, $(x, t) \in G^-$ is the solution of the problem

\begin{align*}
LW_L(x, t) &= 0, \quad (x, t) \in G^-, \\
W_L(x, t) &= 0, \quad (x, t) \in S^\pm \cup S_0^-, \\
W_L(x, t) &= u - U^-, \quad (x, t) \in S^l,
\end{align*}

and finally, the right layer component $W_R(x, t)$, $(x, t) \in G^+$ is the solution of the problem

\begin{align*}
LW_R(x, t) &= 0, \quad (x, t) \in G^+, \\
W_R(x, t) &= 0, \quad (x, t) \in S^\pm \cup S_0^+, \\
W_R(x, t) &= u - U^+, \quad (x, t) \in S^r.
\end{align*}

Now, we analyze the function $U^+e(x, t)$, i.e., the solution of (7). To do that,
we decompose it as
\[
U^{+\varepsilon}(x,t) = U_0(x,t) + \varepsilon U_1(x,t) + \varepsilon^2 v_U(x,t), \quad (x,t) \in \overline{G},
\]
where \(U_i(x,t), i = 0, 1\), are solutions of the problems
\[
\begin{align*}
L_0 U_0(x,t) &\equiv \left\{-b(x,t) \frac{\partial}{\partial t} - r(x,t) \right\} U_0(x,t) = f^{+\varepsilon}(x,t), \quad (x,t) \in \overline{G} \setminus S_0, \\
U_0(x,t) &= \varphi^{+\varepsilon}(x,t), \quad (x,t) \in S_0; \\
L_0 U_1(x,t) &\equiv \left\{-\varepsilon \frac{\partial^2}{\partial x^2} - \frac{\mu}{\varepsilon} x^{2p+1} a(x) \frac{\partial}{\partial x} \right\} U_0(x,t), \quad (x,t) \in \overline{G} \setminus S_0, \\
U_1(x,t) &= 0, \quad (x,t) \in S_0,
\end{align*}
\]
and \(v_U(x,t)\) is the solution of the problem
\[
\begin{align*}
L^\varepsilon v_U(x,t) &\equiv \left\{-\varepsilon \frac{\partial^2}{\partial x^2} - \frac{\mu}{\varepsilon} x^{2p+1} a(x) \frac{\partial}{\partial x} \right\} U_1(x,t), \quad (x,t) \in G, \\
v_U(x,t) &= 0, \quad (x,t) \in S.
\end{align*}
\]
Taking into account that the derivatives of \(U_i(x,t), i = 0, 1\), are bounded uniformly with respect to \(\varepsilon\) and \(\mu\), and using the coarse bounds (4) in (12), we deduce bounds for the partial derivatives of \(U^{+\varepsilon}(x,t)\) on \(\overline{G}^{+\varepsilon}\), and therefore it is straightforward that it holds
\[
\left| \frac{\partial^{k+k_0}}{\partial x^k \partial t^{k_0}} U^{+\varepsilon}(x,t) \right| \leq M \left[1 + \varepsilon^{-k}\right], \quad (x,t) \in \overline{G}^{+\varepsilon}, \quad 0 \leq k + 2k_0 \leq 4. \quad (13)
\]
Now we analyze the interior layer component \(V^{+}(x,t)\). Using (4) and (13), we obtain
\[
\left| \frac{\partial^{k_0}}{\partial t^{k_0}} \varphi^{+\varepsilon}(x,t) \right| \leq M, \quad (x,t) \in S^{\pm}, \quad k_0 = 0, 1, 2.
\]
Defining the barrier function
\[
\varphi_0(x,t) = M \exp(-m_1 \varepsilon^{-1} x), \quad (x,t) \in \overline{G}^+, \quad m_1
\]
is an arbitrary positive constant such that
\[
m_1^2 \leq 2r_0^2, \quad (14)
\]
and $M$ is a constant sufficiently large. Note that
\[
L \phi_0(x, t) = M \exp(-m_1 \varepsilon^{-1} x) \left( m_1^2 - m_1 \mu \frac{\varepsilon}{x} \sigma_{p+1} a(x) - r(x, t) \right) \\
\leq M \exp(-m_1 \varepsilon^{-1} x)(m_1^2 - 2r_0^2) \\
\leq 0.
\]

It follows from the classical minimum principle applied to the domain $\overline{G}^+$ that
\[
\left| \frac{\partial^{k_0}}{\partial t^{k_0}} V^+(x, t) \right| \leq M \exp(-m_1 \varepsilon^{-1} x), \ (x, t) \in \overline{G}^+, \ k_0 = 0, 1, 2, \tag{15}
\]
proving bounds for the derivatives with respect to the time variable.

Lemma 2 provides the following crude bounds for the derivatives of $V^+$ in $x$
\[
\left| \frac{\partial^k}{\partial x^k} V^+(x, t) \right| \leq M \varepsilon^{-k} \ (x, t) \in \overline{G}^+, \ 1 \leq k \leq 4. \tag{16}
\]
Although these bounds are not sharp, they are enough for the analysis of the uniform convergence of our finite difference scheme, since the barrier function $\phi_0(x, t)$ decays exponentially from $x = 0$.

Similarly, for components $U^-(x, t)$ and $V^-(x, t)$ and theirs derivatives, on the set $\overline{G}^-$ we can obtain the bounds
\[
\left| \frac{\partial^{k+k_0}}{\partial x^k \partial t^{k_0}} U^-(x, t) \right| \leq M \left[ 1 + \varepsilon^{2-k} \right], \ (x, t) \in \overline{G}^-, \ 0 \leq k + 2k_0 \leq 4,
\]
\[
\left| \frac{\partial^{k_0}}{\partial t^{k_0}} V^-(x, t) \right| \leq M \exp(m_1 \varepsilon^{-1} x) \ (x, t) \in \overline{G}^-, \ k_0 = 0, 1, 2, \tag{17}
\]
\[
\left| \frac{\partial^k}{\partial x^k} V^-(x, t) \right| \leq M \varepsilon^{-k}, \ (x, t) \in \overline{G}^-, \ 1 \leq k \leq 4.
\]

Now, we study the left singular component $W_L$. We define the function
\[
\phi_1(x, t) = M \exp(-m_1 \varepsilon^{-1} (d + x)) \exp \left( \frac{m_1}{\beta} d^{2p+1} \|a\|_{[-d,0]} t \right), \ (x, t) \in \overline{G}^-,
\]
where $\|a\|_{[-d,0]} = \max_{-d \leq x \leq 0} a(x)$. It satisfies $\phi_1(x, 0) \geq 0, \ \phi_1(-d, t) \geq M, \ \phi_1(0, t) \geq 0,$ and
\[
L \phi_1(x, t) = \phi_1(x, t) \left\{ m_1^2 - r(x, t) \right\} + \left[ -m_1 \frac{\mu}{\varepsilon} x^{2p+1} a(x) - m_1 \frac{b(x, t)}{\beta} d^{2p+1} \|a\|_{[-d,0]} \right].
\]
Note that the expression in the first square brackets is not positive since $m_1^2 \leq 2r_0^2$ and $r(x, t) \geq 2r_0^2$ and the expression in the second square brackets
is not positive since $-d < x < 0$ and $\mu \leq \varepsilon$. Hence,

$$L\phi_1(x, t) \leq 0$$

and, from Lemma 1, it follows

$$|W_L(x, t)| \leq \phi_1(x, t) \leq M \exp(-m_1\varepsilon^{-1}(d + x)), \quad (x, t) \in \Omega^-.$$

Using the same argument as this one for the problems associated to

$$\frac{\partial^{k_0}W_L}{\partial t^{k_0}}, \; k_0 = 1, 2,$$

we obtain

$$\left|\frac{\partial^{k_0}W_L}{\partial t^{k_0}}(x, t)\right| \leq M \exp(-m_1\varepsilon^{-1}(d + x)), \quad (x, t) \in \Omega^-, \; k_0 = 1, 2. \quad (18)$$

Finally, we consider the right singular component $W_R$. Now the barrier function is given by

$$\phi_2(x, t) = M \exp(-m_1\varepsilon^{-1}(d - x)) \exp\left(\frac{m_1}{\beta}d^{2p+1}\|a\|_{[0, d]}t\right), \quad (x, t) \in \Omega^+,$$

with $\|a\|_{[0, d]} = \max_{x \in [0, d]} a(x)$. Then, similarly to the analysis made for $W_L$, we can obtain

$$|W_R(x, t)| \leq \phi_2(x, t) \leq M \exp(-m_1\varepsilon^{-1}(d - x)), \quad (x, t) \in \Omega^+,$$

and

$$\left|\frac{\partial^{k_0}W_R}{\partial t^{k_0}}(x, t)\right| \leq M \exp(-m_1\varepsilon^{-1}(d - x)), \quad (x, t) \in \Omega^+, \; k_0 = 1, 2. \quad (19)$$

We will use again in the analysis of the convergence the crude bounds of the partial derivatives w.r.t. $x$ for both layer components

$$\left|\frac{\partial^kW_L}{\partial x^k}(x, t)\right| \leq M \varepsilon^{-k}, \quad (x, t) \in \Omega^-, \quad \left|\frac{\partial^kW_R}{\partial x^k}(x, t)\right| \leq M \varepsilon^{-k}, \quad (x, t) \in \Omega^+,$$

with $1 \leq k \leq 4$.

**Theorem 1.** Let $u(x, t)$ be the solution of (1) and $U^\pm$ be the regular component, $V^\pm$ be the interior layer component, and $W_R, W_L$ be the right and left boundary layer components given in (5). Then, the estimates (13), (15) (16), (17), (18), (19) and (20) hold, showing the asymptotic behavior of $u(x, t)$ and its derivatives.
where a differential equation, nonuniform grid, given by the difference scheme size is $\delta x$ difference derivatives into five parts $[-d, d]$, $[-d + \sigma, -d]$, $[-\sigma, \sigma]$, $[\sigma, d - \sigma]$ and $[d - \sigma, d]$, where the transition parameter $\sigma$ is defined by $\sigma = \min \left[4^{-1}d, m^{-1}\varepsilon \ln N\right], \quad (21)$ with $0 < m \leq r_0$. We approximate on $G_h$ the problem (1) by the finite difference scheme $\Lambda z(x, t) = f(x, t), \quad (x, t) \in G_h \setminus S_h^\pm,$ $z(x, t) = \varphi(x, t), \quad (x, t) \in S_h,$ $\Lambda^\pm z(x, t) \equiv \varepsilon \left[\delta_x z(x, t) - \delta_x z(x, t)\right] = 0, \quad (x, t) \in S_h^\pm,$ where $\Lambda z(x, t) \equiv \left\{\varepsilon^2 \delta_{xx}^2 + \mu x^{2p+1}u(x) \delta_x^* - b(x, t) \delta_t - r(x, t)\right\} z(x, t),$ $G_h = G \cap G_h, \quad S_h = S \cap G_h, \quad S_h^\pm = S^\pm \cap G_h,$ and $\delta_x^* z(x, t) = \begin{cases} \delta_x z(x, t), \text{ if } x > 0, \\ \delta_x z(x, t), \text{ if } x < 0, \end{cases}$ is the monotone approximation of the first-order derivative $\frac{\partial}{\partial x} u(x, t)$ in the differential equation, $\delta_{xx} z(x, t)$ is the second-order central differences on a nonuniform grid, given by $\delta_{xx} z(x^i, t) = 2 \left(h_i^i + h_i^{i-1}\right)^{-1} \left[\delta_x z(x^i, t) - \delta_x z(x^i, t)\right], \quad (x^i, t) \in G_h,$ $\delta_x z(x, t)$ and $\delta_x z(x, t)$ are the first-order (forward and backward respectively) difference derivatives $\delta_x z(x^i, t) = \left(h_i^i\right)^{-1} \left[z(x^{i+1}, t) - z(x^i, t)\right], \quad \delta_x z(x, t) = \left(h_i^{i-1}\right)^{-1} \left[z(x^i, t) - z(x^{i-1}, t)\right],$ with $h_i^i = x^{i+1} - x^i, \quad h_i^{i-1} = x^i - x^{i-1}, \quad x^i, x^{i+1}, x^{i-1} \in \Omega$ and $\delta_t z(x, t) = \tau^{-1} \left[z(x, t) - z(x, t - \tau)\right], \quad (x, t) \in G_h.$
To prove the uniform convergence of the finite difference scheme (22), we will use the following discrete comparison principle.

**Lemma 3.** The finite difference scheme (22) is $\varepsilon$-uniformly monotone (see, e.g., [2,14]). Moreover, if the functions $z^1(x,t)$, $z^2(x,t)$, $(x,t) \in \mathcal{G}_h$ satisfy the conditions

\[
\Lambda z^1(x,t) \leq \Lambda z^2(x,t), \quad (x,t) \in G_h \setminus S_h^\pm,
\]
\[
\Lambda^\pm z^1(x,t) \leq \Lambda^\pm z^2(x,t), \quad (x,t) \in S_h^\pm,
\]
\[
z^1(x,t) \geq z^2(x,t), \quad (x,t) \in S_h,
\]
then $z^1(x,t) \geq z^2(x,t)$, $(x,t) \in \mathcal{G}_h$.

The main result of the paper is the following.

**Theorem 2.** Let $u(x,t)$ be the solution of (1) and $z(x,t)$ be the solution of the difference scheme (22) on the grid $\mathcal{G}_h$. Assume that $\mu \leq \varepsilon$. Then, the error satisfies the estimate

\[
|u(x,t) - z(x,t)| \leq M \left[ N^{-1} \ln N + N_0^{-1} \right], \quad (x,t) \in \mathcal{G}_h,
\]

i.e., the difference scheme converges uniformly in $\varepsilon$ and $\mu$ with first order in time and almost first order in space.

**PROOF.** In the proof we distinguish two cases.

In the first one, we assume that $\sigma = d/4$, and therefore $\varepsilon^{-1} \leq C \ln N$. The truncation error at the interior points of $G_h$, excluding the interface $S_h^\pm$, is given by

\[
\Lambda(u - z) = \varepsilon^2(\delta_{xx}u - u_{xx}) + \mu a(x) x^{2p+1} (\delta_x^2u - u_x) - b(x,t)(\delta_t^2u - u_t).
\]

Taking Taylor expansions and using the coarse estimates (4), it is straightforward to prove that

\[
|\Lambda(u - z)| \leq M(N^{-1} \ln N + N_0^{-1}), \quad \text{on } G_h \setminus S_h^\pm,
\]
\[
|\Lambda^\pm(u - z)| \leq M N^{-1} \ln N, \quad \text{on } S_h^\pm.
\]

Then, from Lemma 3, it follows

\[
|u - z| \leq M \left( N^{-1} \ln N + N_0^{-1} \right).
\]

In the second case, we assume that $\sigma \neq d/4$. Now, we write the components of the continuous problem as $u = U + V + W_L + W_R$, $U = U^+ \cup U^-$, $V =$
\( V^+ \cup V^- \). Similarly to the continuous problem, we consider a decomposition of the numerical solution as \( z = v + w + w_L + w_R \), \( v = v^+ \cup v^- \), \( w = w^+ \cup w^- \), where the discrete regular component \( v \) is the solution of the problem

\[
\Lambda v = f, \quad \text{in} \ G_h^+ \cup G_h^-, \\
v = U, \quad \text{on} \ (S_0)_h \cup S_h^l \cup S_h^r, \\
\Lambda^\pm v = \varepsilon \left[ \delta_x U^+ - \delta_x U^- \right], \quad \text{on} \ S_h^\pm,
\]

the discrete singular component \( w \) is the solution of the problem

\[
\Lambda w = 0, \quad \text{in} \ G_h^+ \cup G_h^-, \\
w = V = 0, \quad \text{on} \ (S_0)_h \cup S_h^l \cup S_h^r, \\
\Lambda^\pm w = -\Lambda^\pm v \quad \text{on} \ S_h^\pm,
\]

the discrete singular component \( w_L \) satisfies

\[
\Lambda w_L = 0, \quad \text{in} \ G_h^-, \\
w_L = 0, \quad \text{on} \ (S_0^-)_h \cup S_h^+, \\
w_L = W_L \quad \text{on} \ S_h^l,
\]

and the discrete singular component \( w_R \) satisfies

\[
\Lambda w_R = 0, \quad \text{in} \ G_h^+, \\
w_R = 0, \quad \text{on} \ (S_0^+_h)_h \cup S_h^+, \\
w_R = W_R \quad \text{on} \ S_h^r.
\]

Using Taylor expansions, the local error associated to the regular component satisfies

\[
|\Lambda(v - U)| \leq M(\varepsilon N^{-1} + N_0^{-1}), \quad \text{in} \ G_h^+ \cup G_h^-, \\
v - U = 0, \quad \text{on} \ (S_0)_h \cup S_h^l \cup S_h^r, \\
|\Lambda^\pm(v - U)| \leq M \varepsilon N^{-1}, \quad \text{on} \ S_h^\pm,
\]

and therefore, using again the discrete comparison principle, it follows

\[
|(v - U)| \leq M(\varepsilon N^{-1} + N_0^{-1}), \quad \text{on} \ G_h.
\]

Next, we consider the interior layer component. At the boundary, this component satisfies

\[
|(w - V)| = 0, \quad \text{on} \ (S_0)_h \cup S_h^l \cup S_h^r,
\]
and at $S_h^\pm$, we have the estimate
\[ |\Lambda^\pm (w - V)| \leq MN^{-1} \ln N. \] (30)

We study the error for the grid points in $G^+ \cup G^-$. First, we assume that the grid point is such that $|x| \geq \sigma$. Recall that $\sigma = m^{-1}\varepsilon \ln N$. From (15), (17) and choosing $m_1 \geq m$, we obtain
\[ |V(x,t)| \leq M \exp(-m_1|x|/\varepsilon) \leq MN^{-1}. \]

To bound its discrete counterpart, we consider the discrete barrier function
\[
\phi(x^j,t) = \begin{cases} 
N/2 \prod_{i=j+1}^{N/2} \left( 1 + r_0 \frac{h^i}{\varepsilon} \right)^{-1}, & \text{if } 0 \leq j < N/2, \\
1, & \text{if } j = N/2, \\
\prod_{i=N/2+1}^{j} \left( 1 + r_0 \frac{h^i}{\varepsilon} \right)^{-1}, & \text{if } N/2 < j \leq N.
\end{cases}
\]

It satisfies
\[
\varepsilon^2 \delta_x^2 \phi(x^j,t) < 2r_0^2 \phi(x^j,t), \quad \delta_t \phi(x^j,t) > 0, \quad \delta_t \phi(x^j,t) = 0, \quad \text{in } G^-_h, \\
\varepsilon^2 \delta_x^2 \phi(x^j,t) < 2r_0^2 \phi(x^j,t), \quad \delta_x^2 \phi(x^j,t) < 0, \quad \delta_t \phi(x^j,t) = 0, \quad \text{in } G^+_h.
\]

Thus,
\[ \Lambda \phi < 0, \quad \text{in } G^+_h \cup G^-_h, \quad \Lambda^\pm \phi < 0, \quad \text{in } S^\pm_h, \]
and therefore the comparison principle proves the following estimate
\[ |w(x,t)| \leq \phi(x,t) \leq MN^{-r_0/m} \leq MN^{-1}, \]
where we have used that $m \leq r_0$.

From the triangular inequality, we have $|w - V| \leq |w| + |V|$, and therefore
\[ |(w - V)(x,t)| \leq MN^{-1}, \quad |x| \geq \sigma, \quad (x,t) \in G^-_h \cup G^+_h. \] (31)

If the grid point is such that $|x| < \sigma$, taking Taylor expansions, we deduce that
\[
|\Lambda (w - V)(x,t)| \leq M(N^{-1} \ln N + N_0^{-1}), \quad \text{for } |x| < \sigma, \quad (x,t) \in G^-_h \cup G^+_h, \\
|\Lambda^\pm (w - V)(x,t)| \leq MN^{-1} \ln N, \quad \text{for } (x,t) \in S^\pm_h.
\]

Using the discrete comparison principle, now on the interval $[-\sigma, \sigma]$, it follows
\[ |(w - V)(x,t)| \leq M(N^{-1} \ln N + N_0^{-1}), \quad (x,t) \in [-\sigma, \sigma] \cap (G^-_h \cup G^+_h). \] (32)
The boundary layer components \( w_L \) and \( w_R \) are defined in \( G^- \) and \( G^+ \), respectively. Then, the analysis of the convergence of the finite difference scheme on the Shishkin mesh is standard and we have the estimates

\[
| (W_L - w_L) | \leq M (N^{-1} \ln N + N_0^{-1}), \quad \text{in } G^-,
\]
\[
| (W_R - w_R) | \leq M (N^{-1} \ln N + N_0^{-1}), \quad \text{in } G^+.
\]

From the estimates (29), (30), (31), (32) and (33), it follows

\[
| u - z | \leq M (N^{-1} \ln N + N_0^{-1}),
\]

which is the required result.

4 Numerical experiments

In this section, we show the numerical results obtained for the test problem

\[
\begin{cases}
\varepsilon^2 u_{xx} + \mu x^3 (1 + x^2) u_x - u_t - (3 + xt)u = f(x,t), \quad (x,t) \in G \setminus S^\pm, \\
u_x(x + 0, t) - u_x(x - 0, t) = 0, \quad (x,t) \in S^\pm, \\
u(x,t) = 0, \quad (x,t) \in S,
\end{cases}
\]

where \( G = [-1,1] \times [0,1], \) \( S^\pm = \{x = 0\} \times (0,1], \) taking different values of \( \mu \) and

\[
f(x,t) = \begin{cases}
(1 - t^2)(x + e^x), & \text{if } x > 0, \ t \in (0,1], \\
-(1 + t)(x^2 + 1), & \text{if } x < 0, \ t \in (0,1].
\end{cases}
\]

Figure 2 displays the numerical approximation on the piecewise-uniform Shishkin mesh for \( \varepsilon = 10^{-2}, N = N_0 = 32 \) when \( \mu = \varepsilon^{3/2} = 10^{-3} \); from it we see the interior and the boundary layers.

To approximate the numerical errors we use a variant of the double mesh principle (see [8]); the approximated error \( D_{i,n}^{\varepsilon,N,N_0} \) at the grid point \( (x_i, t_n) \) is calculated by

\[
D_{i,n}^{\varepsilon,N,N_0} = \left| U_{i,n}^{\varepsilon,N,N_0} - U_{i,n}^{\varepsilon,2N,2N_0} \right|, \quad i = 0, 1, \ldots, N, \ n = 0, 1, \ldots, N_0,
\]

where \( U_{i,n}^{\varepsilon,N,N_0} \) is the numerical solution obtained on \( G_h \) by using the constant time step \( \tau = 1/N_0 \), and \( (N + 1) \) points in the spatial mesh, and \( U_{i,n}^{\varepsilon,2N,2N_0} \) is the numerical solution when the time step size is \( \tau/2 \), and we take \( (2N + 1) \) points in the spatial mesh, but with the same transition parameter as in the
Fig. 2. Numerical solution of problem (34), (35) for $\varepsilon = 10^{-2}$, $\mu = 10^{-3}$ with $N = N_0 = 32$ on the Shishkin mesh

original mesh $\mathcal{G}_h$. Both numerical solutions are compared in the coarse grid $\mathcal{G}_h$. For each fixed value of $\varepsilon$, the maximum global errors $D^{\varepsilon,N,N_0}$ are estimated by

$$D^{\varepsilon,N,N_0} = \max_{i,n} D_{i,n}^{\varepsilon,N,N_0},$$

and therefore, the numerical orders of convergence $q$ are given by

$$q = q(\varepsilon, N, N_0) = \frac{\log \left( \frac{D^{\varepsilon,N,N_0}}{D^{2\varepsilon,2N,N_0}} \right)}{\log 2}.$$

From these values we obtain the $\varepsilon$-uniform errors $D^{N,N_0}$ and the $\varepsilon$-uniform orders of convergence $q_{uni}$, respectively, by

$$D^{N,N_0} = \max_{\varepsilon} D^{\varepsilon,N,N_0}, \quad q_{uni} = q_{uni}(N, N_0) = \frac{\log \left( \frac{D^{N,N_0}}{D^{2N,2N_0}} \right)}{\log 2}. \quad (36)$$

Results of numerical experiments are given in Tables 1–4, where, for simplicity, we take $N = N_0$.

Table 1 displays the results on a uniform mesh and $\mu = \varepsilon^{3/2}$; from it, we see that the solution of a difference scheme on a uniform mesh does not converge $\varepsilon$-uniformly.

Table 2 displays the numerical results for errors in the solution of the difference scheme (22) on the piecewise uniform Shishkin mesh in $x$ taking $m = 1/2$ with $\mu = \varepsilon^{3/2}$. This table shows that the solution of the scheme converges $\varepsilon$-uniformly with order of the convergence rate close to one in agreement with the theoretical estimate.

In Tables 3 and 4, the numerical results are given for the same difference scheme as in Table 2 but with $\mu = \varepsilon$ in Table 3 and with $\mu = \varepsilon^2$ in Table
Table 1

Maximum errors and orders of convergence on a uniform mesh when $\mu = \varepsilon^{3/2}$

</table>

4. We have chosen $m = 1/2$ in (21) to define the Shishkin mesh. From these results it follows that the difference schemes converge $\varepsilon$-uniformly with order of the convergence rate not lower than 0.68 in Table 3 and 1.04 in Table 4.

From results in Tables 2, 3 and 4, it is seen that the rate of the $\varepsilon$-uniform convergence decreases with growth of $\mu$.

Thus, the results of numerical experiments are in agreement with the theoretical estimate.
